KEY TERMS AND DEFINITIONS

Chemical Oxygen Demand: Amount of oxygen required to oxidize both organic and inorganic substances in wastewaters.

Electrochemical Treatment Technique: Any process either caused or accompanied by the passage of an electric current and involving in most cases the transfer of electrons between two substances—one a solid and the other a liquid

Electrocoagulation: Is a broad-spectrum treatment technology that removes total suspended solids (TSS), heavy metals, emulsified oils, bacteria and other contaminants from water (is a technique used for wash water treatment, wastewater treatment, industrial processed water, and medical treatment).

Electrodeposition: Is a process that uses an electric current to reduce dissolved metal cations so that they form a thin coherent metal coating on an electrode.

Electroflotation: Is a process of floating of pollutants to water surface by tiny bubbles of hydrogen and oxygen gases generated from water electrolysis. Electroflotation module consists of electroflotator with insoluble electrodes, tanks for alkali and flocculant solutions, pumps, rectifier, sludge collecting system (Skimmer).

Electrophoretic Deposition: Is a term for a broad range of industrial processes which includes electrocoating, cathodic electrodeposition, anodic electrodeposition, and electrophoretic coating, or electrophoretic painting.

Emerging Pollutants (EPs): Synthetic or naturally occurring chemicals that are not commonly monitored in the environment, but which have the potential to enter the environment and cause known or suspected adverse ecological and (or) human health effects.

Ozonation Treatment: Oxidation process that requires the use of ozone.

Design and Implementation of a Location-Based Service With Emphasis on a Geographical Database

Wen-Chen Hu

University of North Dakota, USA

INTRODUCTION

Smartphones are the most popular electronic devices nowadays. People use them to perform daily activities, like managing messages and emails, browsing the mobile Internet, and watching video, anywhere and anytime. One of the popular apps is location-based service (LBS), which is a service based on the geographical position of a mobile handheld device. One of the LBS examples is to find a nearby ethnic restaurant by using a smartphone. According to the market research reports, (i) the global LBSs market was valued at \$11,994 million in 2016, and is expected to reach \$61,897 million by 2022, supported by a growth rate of 26.6% (Malani, 2017), and (ii) the growing trend for the integration of location-based search with social networking websites will post a growth rate of close to 40% for the global LBS market during 2017-2021 (Technavio, 2017). They show the high importance and popularity of LBSs. However, building an LBS is not a simple task. This research tries to help developers by showing how to build an LBS.

Building a location-based system (LBS) is not easy because various disciplines and subjects are involved. This article tries to mitigate the high complication and difficulty by showing how to build an LBS from the ground up with a focus on connecting the mobile devices to a server-side geographical database. The five major components of an LBS system and our methods for implementing them are listed below:

- *Mobile handheld devices:* Android emulator (AVD), instead of a smartphone, is used for development.
- *Positioning systems like satellites:* The DDMS (Dalvik Debug Monitor Server) of an AVD is employed to send the mock locations, instead of using actual road testing.
- *Mobile and wireless networks:* URL connection, provided by Android, is used to connect the emulator to the service provider.
- *Service providers:* The LBS is to show a direction between the user and the nearest participant.
- *Geographical databases:* A small geographical database is used by the service provider.

Readers, who are interested in LBS research and applications, can use this paper to build their LBS prototypes. Based on the prototypes, they can realize their LBS research and show the advantages of their proposed methods.

The rest of this paper is organized as follows. Section 2 introduces related software, tools, and services including (i) Android and Android Studio, (ii) MySQL and MySQL Workbench, and (iii) various location-based services. The proposed LBS app is introduced in Section 3, which includes three

DOI: 10.4018/978-1-7998-3479-3.ch094

sub-sections: (i) the proposed system, (ii) the server-side geographical database used by the proposed system, and (iii) the result screenshots. Section 4 explains how to build the proposed system including three sub-section: (i) Android server connection, (ii) client-side code, and (iii) server-side code. The final section summarizes this study and gives possible LBS projects.

BACKGROUND

This section introduces the software and tools used to build the proposed system including (i) Android and Android Studio and (ii) MySQL databases and MySQL Workbench. In addition, various location-based services are listed to give readers an idea what the market trend of LBSs is.

Android and Android Studio

Android (Android, n.d.a) is the most popular mobile operating system as it is used by more than 80% of smartphones in 2017 (IDC, 2018). It is a software stack based on the Linux kernel for mobile devices that includes an operating system, middleware, emulators, and various key applications like phone, browser, and contacts. It was initially developed by Android, Inc., which was acquired by Google, Inc. in 2005. Since then, Android has been revised and enhanced significantly and constantly for the ever-changing newer features of mobile devices. In the past, Android app development in Eclipse with ADT (Android Development Tools) was highly recommended. Since 2014, Android Studio (Android, n.d.b) became the primary IDE (Integrated Development Environment) for native Android application development. It is freely available under the Apache License 2.0 based on JetBrains' IntelliJ IDEA software. Figure 1 shows a user interface of Android Studio and its major functions are listed as follows:

- *Attributes*, providing controls for the selected view's attributes,
- *Design editor*, displaying the layout in both the design and blueprint views,
- *Gradle console*, a screen for managing the automated build system for the Android source code,
- *Logcat*, a screen showing the logs generated from the running programs,
- *Menu bar*, providing the essential functions of Android Studio,

Figure 1. A user interface of Android Studio

- *Palette*, providing a list of widgets and layouts that can be dragged into the layout in the editor,
- *Project structure*, showing the view hierarchy of the project, and
- *Toolbar*, providing buttons to configure the layout appearance in the editor and to change some layout attributes.

MySQL Databases and MySQL Workbench

The proposed geographical database uses MySQL (MySQL, n.d.a), an open-source relational database management system (RDBMS). It is supported by a company named MySQL AB, which is a division of Oracle Corporation now. MySQL is one of the major components of LAMP (Linux, Apache, MySQL, and PHP/Perl/Python) technology for website construction. It is reliable because tens of thousands of websites have used MySQL without incidences and, even better, it is free because it is open source. In addition, most programming languages like PHP and Perl are allowed to embed SQL (Structured Query Language) commands in their programs for adding, accessing, and processing data in MySQL. This research uses Android Java to connect to a server-side PHP program with embedded SQL commands to access the geographical database using MySQL. Other than using MySQL text user interface to manage MySQL, MySQL Workbench (MySQL, n.d.b) is a database IDE (Integrated Development Environment) for the MySQL database systems. It allows a DBA or developer to visually design, develop, manage, and maintain databases. Figure 2 shows a user interface of the MySQL Workbench and its major components are introduced as follows:

- *Hide/show panels*, changing the layout of the Workbench,
- *Menu bar*, providing the essential functions of MySQL Workbench,
- *Navigator*, showing the schema of the user,
- *Object information*, displaying the details of the object,
- *Output*, containing the log of executed commands,
- *Result*, showing output from the SQL commands in the query panel,
- *SQL additions*, including context help and SQL snippets for saving SQL code,
- *SQL query panel*, allowing users to enter SQL commands, and
- *Toolbar*, providing buttons to quickly manage the SQL commands in the query panel.

Figure 2. A user interface of MySQL Workbench

Location-Based Services (LBSs)

Various LBSs are available on the app stores and most major IT corporations provide their own LBSs. This sub-section introduces some of them, so readers can get a sense of what LBSs can affect our daily lives and implement their own LBSs based on this research:

- Foursquare (<https://foursquare.com/>), recommending interesting places like coffee houses, restaurants, and stores to users based on their previous browsing history, purchases, or check-in history.
- Uber (<https://www.uber.com/>), a form of sharing economy and of which major function is ride-sharing among its users.
- Google Maps (<https://maps.google.com/>), a web mapping service developed by Google. Other than the traditional map services like street maps and route planning for traveling, it also provides various recommendations such as restaurants and hotels.
- Bing Maps (<https://www.bing.com/maps/>), provided by Microsoft including the features of directions, traffic information, and people, business, and location search.
- iOS – Maps (<https://www.apple.com/ios/maps/>), a map or location-based service provided by Apple, Inc. including the features of indoor maps, navigation, and proactive suggestions.
- AutoNavi (<https://www.autonavi.com/>), a provider of digital map, navigation, and LBS in China offering products with features such as route planning, travel navigation, and offline maps from the Alibaba Group.

DESIGN OF THE PROPOSED LOCATION-BASED SERVICE (LBS)

Various LBSs can be found from the app stores. Examples of the services include finding nearby ethnic restaurants, navigation, and recommending interesting places or events. Other than the app user, most participants of the services are static or fixed; i.e., they, like the restaurants and concerts, are not mobile. This research investigates a kind of LBSs of which the participants are mobile. The potential of this kind of LBSs are great, but at the same time, their realization is different from the one of the traditional LBSs. This section introduces the design of the proposed system and implementation of the system will be given in the next section.

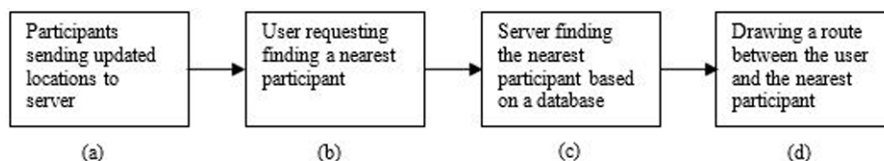

The Proposed System

The proposed location-based service is to draw a direction between the user and the nearest mobile participant. The major difference between the proposed system and other LBS systems is the participants of the former system are mobile. For example, a student is looking for his/her friends to borrow a calculator right before an exam. Traditional way to solve this problem is to find the nearest place where his/her friends live. However, the problem is his/her friends may be on the move and their locations may be different from time to time. The services would not be effective if the mobility feature is not considered. One way to keep track of the participants' locations is having the participants send their locations to the server once they move and the locations are saved in a server-side geographical database. The service then retrieves the current locations from the database and draws a direction between the user and the nearest participant. The following steps show how the proposed service works:

1. Participants sign up the service.
2. Entries are created in tables of a server-side geographical database.
3. Participants send their locations to the server if their locations change.
4. The database is updated according to the received location data.
5. A user submits his/her current location and a request to find a nearest participant.
6. Based on the requester's current location and the location data in the geographical database, the service draws a direction between the user and the nearest participant.

Figure 3 gives another way to explain the proposed service by giving a workflow of the proposed system. It includes the following four steps: (a) participants sending their updated location data to the sever, (b) the user looking for a nearest participant, (c) the server finding the nearest participant according to the locations of user and participants, and (d) drawing a route between the user and the nearest participant.

Figure 3. Workflow of the proposed system

The Proposed Server-Side Geographical Database

Geographical databases are databases storing geographic data including spatial data, like heights and locations, and attribute data like names such as McDonalds and functions such as restaurant. They are usually provided by a third party such as GeoNames (n.d.) because huge space is needed to store the data. This section proposes a small geographical database for facilitating geographic data storage, indexing, searching, and matching. This research uses a server-side MySQL (n.d.a) database to host the geographic data with an emphasis on mobile users. The database schema is shown in Table 1. It is made as simple as possible because the focus is on how to connect the mobile client to a server-side geographical database. The major difference between the proposed database and traditional databases

Table 1. Sample values of the proposed geographical database schema including (a) entities table and (b) LBS table

PID	Name	Function	Latitude	Longitude	Time	LBS	PID
1	Poke Mon	male	47° 55' 31" N	97° 2' 57" W	2019-02-09 21:21:40	1	1
2	Italian Moon	restaurant	47° 55' 40" N	97° 1' 60" W	2010-10-29 06:28:42	12	3
3	Super Mario	male	47° 55' 31" N	97° 1' 52" W	2017-05-28 10:51:30	2	4
4	GI Jane	female	47° 55' 60" N	97° 1' 98" W	2018-02-29 11:18:42	1	32
5	Valley Dairy	gas station	47° 55' 33" N	97° 2' 53" W	2017-03-37 06:21:43	4	120
6	Turtle River	park	47° 54' 72" N	97° 1' 70" W	1991-12-20 04:40:42	2	3
7	GF Bus	transportation	47° 55' 51" N	97° 1' 54" W	2019-02-54 10:33:21	1	3
8	Florida Sunshine	farmers' market	47° 55' 31" N	97° 1' 97" W	2018-06-29 19:21:44	...	...
(a)							(b)

is the entity could be mobile; i.e., its location could change from time to time. It consists of two tables: *entities* and *LBS* tables. The table *entities* include a column *time*, which is the time when the location is saved. The duration of the entity at the current location can therefore be found as the difference between the current time and the saved time. One of the functions of the duration is to check whether the location is valid. For example, if the duration of the location is more than a week, then the service may assume the mobile location is not valid. The other table *LBS* is used to find the participants of an instance of the service. One participant may join more than one instance of the service.

The Result Screenshots

This sub-section shows some of the screenshots from this service. It is to help readers understand what the service can achieve before they study the implementation details given in the next section. Instead of doing actual road tests, this research uses Android AVD (Android Virtual Device) to simulate the testing. Figure 4 shows three screenshots from this app. Figure 4.a shows the app in the Android Launcher, Figure 4.b is the control panel associated with the emulator, and Figure 4.c is the extended controls after clicking the item at the bottom of the control panel. The extended controls include a location function, which allows users to enter location data including latitude, longitude, and attitude and submit it to the app. Using this function is similar to the app receiving location data from the GPS (Global Positioning System).

Figure 4. (a) The proposed app shown in the Android launcher, (b) the control panel, and (c) the extended controls

Figure 5 shows an example of an application of this service, where the user is marked in Figure 5.a, Figure 5.b shows two more participants joining the service, and a direction between the user and the nearest participant is drawn in Figure 5.c. Another example is given in Figure 6, which is similar to the one in Figure 5, but with five participants.

Figure 5. (a) User marked, (b) two more participants joining the service, (c) direction between the user and the nearest participant

Figure 6. Another Example: (a) user marked, (b) five more participants joining the service, and (c) direction between the user and the nearest participant

IMPLEMENTATION OF THE PROPOSED SYSTEM

Design of the proposed system is given in the previous section and this section discusses the implementation part. Several programming languages are used in this implementation where Android Java is mainly used on the client-side for direction drawing, and PHP and Python are used on the server-side for accessing the geographical database and calling Google Maps Directions API (Application Programming Interface) (Google, n.d.) to find the shortest distance. Figure 7 shows a workflow of the implementation of the proposed system including (i) a user requesting a direction between him/her and the nearest participant, (ii) location data of the participants retrieved from the geographical database, (iii) the distances between the user and the participants calculated by using Google Maps Directions API, (iv) the data of the nearest participant sent to the user, and (v) the shortest direction drawn by using Google Directions API. Brief discussion of the implementation is given in this section. Further references for the related implementation can be found from the articles by the authors (Hu, 2018; Hu, Kaabouch, Yang, & Wang, 2014; Hu, Kaabouch, & Yang, 2014).

Figure 7. Workflow of the proposed system implementation

Android Server Connection

There are a couple of ways allowing Android devices to connect to the servers. Three of the classes for the connections are given as follows:

- `URLConnection`, which represents a communications link between the application and a URL,
- `HttpClient`, which is an interface for an HTTP client and was deprecated in android 5.1 and is removed from the Android SDK (Software Development Kit) in Android 6.0, and
- `HttpURLConnection`, which is the preferred method to connect to a remote server through HTTP.

This research connects a mobile client to the server via the `HttpURLConnection` class. The connection allows the client to send its location data to the server and receive the information in a JSON format the server offers. It is also used to connect to the Google Maps Directions server to request a route between the user and the nearest participant. Program 1 shows a code snippet used to connect to the server and receive data from the server.

```

private ArrayList<LatLng> downloadUrl(LatLng user_location) {
    HttpURLConnection urlConnection = null;
    URL url = new URL("ADDRESS_TO_SERVICE_SERVER_WITH_DEVICE_LOCATION");
    // Creating an HTTP connection to communicate with the URL
    urlConnection = (HttpURLConnection) url.openConnection();
    // Connecting to the URL
    urlConnection.connect();
    // Reading data from the URL
    while((line = br.readLine()) != null) {
        String[] latlong = line.split(",");
        double latitude = Double.parseDouble(latlong[0]);
        double longitude = Double.parseDouble(latlong[1]);
        LatLng loc = new LatLng(latitude, longitude);
        data.add(loc);
    }
}

```

Program 1. Code snippet for server connection

JSON stands for *JavaScript Object Notation*. It, much like XML, is syntax for storing and exchanging text information. This application parses JSON files returned from Google Maps Directions via web services and extracts map data from it. Program 2 shows a code snippet used to connect to the Google

Maps Directions service for drawing a direction between the user and the nearest participant. A URL for web services is built to request and retrieve the Google Maps Directions data in a JSON format. An example is given as follows:

```
https://maps.googleapis.com/maps/api/directions/json
?origin=37.422006,-122.084095
&destination=37.431098,-122.234912&sensor=false
private String downloadJSON(LatLng user_location, LatLng other_user_location)
{
    HttpURLConnection urlConnection = null;
    URL url = new URL("https://maps.googleapis.com/maps/api/directions/
json?origin=" +
        user_location.latitude      + "," + user_location.longitude + "&desti-
nation=" +
        other_user_location.latitude + "," + other_user_location.longitude +
        "&key=GOOGLE_API_KEY");
    // Creating an HTTP connection to communicate with the URL
    urlConnection = (HttpURLConnection) url.openConnection();
    // Connecting to the URL
    urlConnection.connect();
    // Reading data from the URL
    while ((line = br.readLine()) != null) { sb.append(line); }
```

Program 2. Code snippet of using web service for Google Maps Directions

The Client-Side Code

Program 3 shows a client-side code snippet for the following two major functions:

- Receive data from the server.
- Use the data to draw the direction between the user and the nearest participant and mark all participants.

The `doInBackground` method is used to request and retrieve the Google Maps Directions data in a JSON format by using web services. The `onPostExecute` method is used to parse the JSON string returned from the `doInBackground` method.

```
private class ChangeLoc extends AsyncTask <Location, Void, String> {
    @Override
    protected String doInBackground(Location... params) {
        mLatitude = params[0].getLatitude();
        mLongitude = params[0].getLongitude();
        final LatLng point = new LatLng(mLatitude, mLongitude);
        runOnUiThread(new Runnable() {
            @Override
```

```

    public void run() {
        mGoogleMap.moveCamera(CameraUpdateFactory.newLatLng(point));
        mGoogleMap.animateCamera(CameraUpdateFactory.zoomTo(12));
    }
});
ArrayList<LatLng> data = new ArrayList();
// Fetching the information of other users from web service
data = downloadUrl(point);
data.add(new LatLng(mLatitude, mLongitude));

// Drawing the marker, if destination location is not set
final ArrayList<LatLng> finalData = data;

runOnUiThread(new Runnable() {
    @Override
    public void run() { drawMarker(data); }
});
LatLng other_user_point = new LatLng(data.get(0).latitude, data.get(0).
longitude);
String results = "";
// Fetching the route from web service (Google Maps Directions)
results = downloadJSON(point, other_user_point);
return results;
}
// Executing in UI thread, after the execution of doInBackground()
@Override
protected void onPostExecute(String result) {
    super.onPostExecute(result);
    ParserTask parserTask = new ParserTask();
    // Invoking the thread for parsing the JSON data.
    parserTask.execute(result);
} // End of onPostExecute
}

```

Program 3. Client-side code snippet

The Server-Side Code

The server-side code includes the following two functions:

- Retrieve the participants' locations from the geographical database by using PHP.
- Find the shortest distance by using Python shown in Program 4.

Python and PHP are used because Python is convenient in text and array processing and PHP is recommended for web processing. The shortest distance is found by finding the distance between the user and each participant and comparing the distances.

```
users_locs = sys.argv[1].split(':'); # Receiving other users' locations
## Iterating for user locations
for distan in users_locs:
    url = 'https://maps.googleapis.com/maps/api/directions/json?origin='
        + origin + '&destination=' + distan + '&key=' + api_key
    ## Receiving the JSON object from Google Maps Directions
    f = urllib.urlopen(url)
    string = f.read()
    ## Parsing the JSON object
    j = J.loads(string)
    ## Receiving the distance
    dist = int(j["routes"][0]["legs"][0]["distance"]["value"])
    Distances.append(dist)
    ## Returning the user locations in an ascending order
for i in sorted(Distances):
    print users_locs[ Distances.index(i) ]
```

Program 4. Server-side code snippet

FUTURE RESEARCH DIRECTIONS

This research will have broader and important impacts on location-based research and services, as well as computer science education. Curriculum development and research initiatives will benefit from this research. This project involves a variety of topics and could be used to enhance curriculum development and for class projects. Readers may apply the knowledge and technologies learned from this article to the following suggested research or applications:

- Finding the interesting nearby places such as ethnic restaurants and movie theaters,
- Providing various recommendations such as concerts and museums including driving/walking routes,
- Using social networks to connect people on the move within a short distance,
- Location-based promotions and coupons such as sales and discounts, and
- Indoor positioning and navigation used to help users have a better visiting experience.

Other than the above suggested research areas, another critical issue about location-based services is security and privacy, which are considered difficult. For example, the service providers need the location data from the users in order to provide services. However, once the location data is shared with the providers, the user privacy may be violated. Without rigorous security and privacy, users would be reluctant to adopt the services. Related security and privacy research can be found in the Additional Reading section below.

CONCLUSION

10

Location-based services (LBSs), such as location-based social networks, navigation, and human behavior study and recognition, have already made a great impact on our daily lives. One of the major components of an LBS is the geographical database, which stores a huge amount of geographical data like restaurant and landmark information. The service providers use the data from the geographical databases to answer users' requests. This article pragmatically discusses the design and implementation of a location-based service, which includes five major components: (i) mobile handheld devices, (ii) positioning systems like satellites, (iii) mobile and wireless networks, (iv) service providers, and (v) geographical databases. The discussion covers the five components, but with emphasis on the geographical database. Readers will not have problems creating a location-based service after studying this article. Other than server-side databases, readers may consider using client-side databases like SQLite (n.d.) for mobile devices. However, the major problem of employing client-side databases is their storage sizes are usually not enough for geographical data.

KEY TERMS AND DEFINITIONS

Android: Android, developed by the Open Handset Alliance led by Google, is a software stack for mobile devices that includes an operating system, middleware, and key applications.

Android Studio: Since 2014, Android Studio became the primary IDE (Integrated Development Environment) for native Android application development. It is free software under the Apache License 2.0 developed by Google. It includes the following features: (i) intelligent code editor, (ii) code templates and GitHub integration, (iii) multi-screen app development, (iv) virtual devices for all shapes and sizes, and (v) Android builds evolved, with Gradle.

Client-Server Architecture: It is a computing model including servers (the resource or service providers) and clients (the service requesters), where the server hosts, manages, and delivers the resources and services to be used by the client. For example, the electronic commerce systems are usually implemented by using a three-tier client-server architecture, where the server is the e-commerce provider (computing facilities) and the client is the end users (browsers).

Geographical Databases: They are databases storing a huge amount of geographical data such as information about restaurants and hotels. Service providers usually do not store and maintain all the information requested by users. Instead, geographical data and location information data are usually supplied by a third-party provider like a maintaining authority (e.g., mapping agencies) or business and industry partners (e.g., yellow pages).

Location-Based Services (LBSs): A location-based service is a service based on the geographical position of a mobile handheld device. One of the LBS examples is to find a nearby ethnic restaurant by using a smartphone.

MySQL Databases: They are open source relational database management systems (RDBMS) that use Structured Query Language (SQL), the most popular language for adding, accessing, and processing data in a database.

MySQL Workbench: MySQL Workbench, a unified visual tool, allows database architects, developers, and DBAs to perform various database management functions including data modeling, SQL development, user administration, and backup.

SQLite Databases: SQLite is an open source embeddable relational database management system. It supports most of the SQL-92 standard, has support for the major languages, and runs on all major operating systems. The SQL statements are compiled into assembly, which is executed in the SQLite virtual machine, the Virtual Database Engine (VDBE).

Climate Change: Inclusion of Gender and Cultural Diversity in Climate Change Actions

Mgbeodichinma Eucharia Onuoha Oragwa

Technical University of Mining Bergakademie Freiberg, Germany

INTRODUCTION

Climate change has influenced horticulture fundamentally, especially diminishments in soil water accessibility, impacts of hoisted CO₂ movements of warm and dampness limits to cropping, effect on drought, warm anxiety and different extremes, impacts on nuisances, weeds and ailments, and effects on soil fruitfulness. The question is no longer how much global warming and climate change rather what are the impacts and what ought to be done about it? To the later, the only way is by choosing to act with a sense of urgency starting from encouraging awareness of importance of gender and cultural diversity inclusion in climate actions, to energy policy reform down to mitigation and Adaptation measures (OECD/IEA, 2001).

However, Martin-Luther king's words four decade back still hold an intense reverberation in this twenty-first century where we are still faced with the savage urgency of a crisis that connects today and tomorrow; that is climate change crisis (UNDP, 2007/2008). *Climate change* is the characterizing human advancement issue of our age. All development is eventually about growing human potential and extending human freedom. It is about individuals building up the abilities that engage them to settle on decisions and to lead experience that they esteem. Climate change debilitates to dissolve human freedoms and limit choice. It raises doubt about the principle rule that human advance will make the future look better than the past (UNDP, 2007/2008). Moreover, since the peak of public mindfulness in the mid-1990s the global environmental issue known as climate change has been developing and changing quickly as of late (Sanderson et al., 2007). One of the most important factors, has been the inclusion of gender and cultural diversity in climate actions which in the past was either disregarded or given as an after-thought in the overall environmental change debate, while now it has become a more important hypothetical and policy issues (UNDP, 2011).

As climate is changing, culture is changing also (Wisner B., 2010). Across cultures, the effects of environmental change influenced women and men differently. Although women are excessively affected by environmental change, they assume a key role in adapting and mitigating climate change (UNDP Bangkok Regional Hub, 2019). For example, in the developing nations, women typically have the responsibility of gathering and generating food, collecting water and sourcing fuel for heating and cooking but with environmental change extrem events, these duties become harder to some women in the globe. Due to the above mentioned activities of some of these women in the globe, they are exposed with the knowledge and understanding of what is required to adapt to altering environmental circumstances and discovering practical solutions (UNDP Bangkok Regional Hub, 2019). *Culture* according to van den pol is generally defined as a total of meanings and knowledge that human beings required to operate in a

certain situation, for example, understanding of language, practices, rituals, views, values & norms etc. (Van den Pol, 2010).

Cultural diversity and climate change are two inseparable situations in the sense that, due to global warming: horticulture decreases and the generation of environmental refugees increases as a result of search for food and greener pastures, disruption of cultural continuity due to enhanced mortality from infectious diseases, mental dysfunction, stunted child development from malnutrition and the disruption of family life (Hoff, 2002). Knowing the importance of gender and cultural diversity, this article tends to promote more awareness to the importance of its inclusion on climate actions. Also note, that environmental change and climate change will be used in this paper as a synonym; the word 'Inclusion' also refers to 'consideration' in this paper.

BACKGROUND

As already mentioned above, in the developing nations, women typically have responsibility of gathering and generating food, collecting water and sourcing fuel for heating and cooking. With climate change, these tasks have become more harder due to extreme weather events such as diminishments in soil water accessibility, impacts of hoisted CO₂ movements of warm and dampness limits to cropping, effect on drought, warm anxiety and different extremes, impacts on nuisances, weeds and ailments, and effects on soil fruitfulness (UNDP Bangkok Regional Hub, 2019). To further discuss the connection between climate change, gender and climate finance, this section is divided into the following subsection:

Connectivity of Climate Change and Cultural Diversity

As already mentioned, to provide an appropriate solution to climate change, a cross-cultural communication is necessary as noted by Bernadet van den pol, since people from various countries, with various background, have to exchange their ideas and opinions about how to solve this problem (Van den Pol, 2010). As van de Pol is defining culture as a meaning or knowledge that human beings need to function in a certain situation, Keesing (1974) in his article is distinguishing between culture as an ideational system and culture as an integrated adaptive socio cultural system. Keesing further argued that as an ideational framework, culture is basically in the head of an aggregate mind and it only alludes to recognitions, convictions, standards and values. Culture in this setting can be utilized to explain social practices and their interrelation among thoughts and practices (Angula et al., 2014). For example, Angula et al. in their research observed that: the cultural beliefs, observation and view that perceive women as a frail and subordinate to a man still overwhelm the Namibian culture. Looking at the elements that upgrades vulnerability to environmental change such as: Decision making, access to information, assets, financial resources and technical skills, women in Namibia still have limited power at all degrees of administration (Angula et al., 2014).

However, climate change has various impact on culture. Climate change as known includes the interactions of numerous systems such as the air, hydrosphere, cryosphere and biosphere, each of which is enormously intricate in its possess right. The immediate desposition of rural people by huge scale projects attempted by government as a reaction to upgrade climate circumstances or clashes over water and arable land could be one cause of cultural interruption (Wisner B., 2010). Nevertheless, the combined consequences on water supply, illness patterns, cultivating framework and the habitability of seashores settlements have a cultural effects on the effected. Additionally, climate change has both irregular,

outrageous effects like enormous storms and heat waves, unavoidable, aggregate impacts like the annihilation of living things and the ascent of sea level. Both kinds of impacts as noted by Wisner have a role in dislodging human populace and interrupting their livelihoods and culture (Wisner B., 2010).

Also, irresistible disease pathogens like creepy crawlies and bacteria thrive in warmer atmosphere. The most affected are the vulnerable populations such as natives cultures, economically depleted groups and societies, and island countries. The variety of societies and human advancement that have developed over hundreds of years cannot be clarified without considering the impact of provincial ecological assets and overall local condition (Hoff, 2002). For instance: the atmosphere and soil, the type of water supplies, the biotic inhabitants of a local area, and other natural highlights that thoroughly formed the propensities, innovation, work, entertainment, travel, nourishment, and other cultural adaptations in uniquely various ways around the world are effected. Further instance where global warming impacts human culture is also found in the change of horticultural practices. For instance, unlike before, Asian civilizations were culturally based on rice; meso-American on Maize; the Peru on Potatoes, and European on wheat and other cereals; today the reverse is the case in the sense that production /manufacturing of food can no longer be describe as a culture to some extent (Hoff, 2002). These diverse effect on culture impacts cultural transmission particularly in rustic territories and among minority language bunches officially under stress due to economic globalisation, the urban float of the youthful and long period of disregard or even antagonistic vibe by those responsible of government language, training and cultural arrangements (Williams et al., 2013).

Connectivity of Climate Change and Gender

According to World Health Organization, *Gender* in the context of climate change is described as socially constructed norms, roles and relations that a given society considers appropriate for men and women. Gender determines what is permitted and valued in a woman or a man in a determined context (WHO, 2014). In the horticultural sector, provincial women in developing nations are the essential producers of staple nourishment, a sector that is profoundly bare to the dangers that accompany drought and unsure precipitation. In many nations, climate change implies that women and young girls need to walk further to gather water, particularly in the dry season. Women in Sub-Saharan Africa, as noted by UNDP go through 40 billion hours per year gathering water; and at the same time, expected to contribute much of the unpaid labor that will go into adapting to climate dangers through soil and water preservation, the building of anti-flood dikes, and increased off-farm business (UNDP, 2009).

Nevertheless, the negative effects of climate change can be felt in the present through catastrophic events such as avalanches, floods and hurricanes; and in the long haul, through increasingly progressive debasement of nature. The unfavorable effects of these events are already felt in numerous regions, including in regard to, entomb alia, farming and sustenance security; biodiversity and biological system; water assets; human wellbeing; human settlements and relocation patterns; and energy, transport and industry (UN Women Watch, 2009). In many of these cases as further described by UN Women Watch, women are more vulnerable to their effects than men due to the role they play in various regions of the globe. For instance: taking a gander at the territory of sustenance security, climate change has four noteworthy repercussions known, as described by UN Women Watch, namely: nourishment availability, nourishment accessibility, sustenance uses and nourishment frameworks dependability. Women agrarians presently account for 45-80% of all food manufacturing in the developing nations depending on the district; about 2/3 of these work powers are women in the developing nations and over 90% of them in

various African nations are occupied in agrarian work. Thereby making conventional sustenance sources to become increasingly capricious and scarcer (UN Women Watch, 2009).

The acknowledgement that vulnerability and reaction to environmental change impacts among men and women is not the same prompted the notion of gender dimensions in climate change dialogue and research. Effects of climate change are not gender unbiased; that is to say, gender roles are socially built and have generated disparity among men and women. The various roles that women and men play in societies and families are endangered to climate risks in numerous ways and this differentiates the vulnerability of women and men that are been affected by climate change. Additionally, the dependency of men and women on natural resources also make them vulnerable to climate change impacts (Angula et al., 2014).

Nonetheless, there is a significant interplay among environmental change, gender equality, women's empowerment, and accomplishment of the Millennium Development Goals. Environmental Change adaptation and mitigation endeavors legitimately influence advancement outcomes including issues of gender equality (UNDP, 2011). Moreover, policies that are educated by and respond to both women and men practical and strategic needs can lead to increasingly compelling climate responses as well as improvement across advancement goals. Beside, the design of the on-coming climate finance architecture plays a key role in whether or not, climate responses create sustainable development, including steps towards greater gender equality and women empowerment, or whether they inflame procedures that detriment women and strengthen historical or structural prejudice (UNDP, 2011).

Consequently, the World Health Organization records demonstrated that many of the health risks that are probably to be influenced by progressing climate change also show gender differentials. These distinctions are found in exposure to the aberrant and longer haul impacts of climate – related risks. For example, droughts in developing nations bring health risks through decrease accessibility of water for drinking, cooking and cleanliness, and through nourishment uncertainty. Women and their offspring unduly suffer health consequences of nutritional deficiencies and the burdens associated with travelling further to collect water (WHO, 2014). As a result of that, as noted by UNHCR, movement of populace given the ultimate changes and catastrophes could hinder and limit the conveniences of women and girls training as men emigration increment significantly living the burdens for their women and their children (Aguilar, et al., 2007).

Importance of Cultural Diversity consideration in Climate Change Actions

Having defined culture above, *diversity* is broadly defined to incorporate contracts in race, gender, national inception, ethnicity, capacity, and even geographical root. Cultural diversity are thus imparted through style, rules, shared significance, and even lingos, and the might be seen as contrasts by others in communication (Larkey, 1996). Native people are increasingly perceived to have impressive insight on issues identified with environmental change adaption. Studies have shown the value of indigenous peoples' perceptions of change in climate-related atmospher design, sea phenomena, and fire conduct. Their insight into past environmental motif can help remake historical benchmark. Cultural ecological insight of environmental health and species conveyances can contribute to customary suitable adaptation. Customary water-related insight, water collecting and cache have enabled indigenous people to endure in arid avalanche and adapt with drought for centuries (Williams et al., 2013). Van den Pol in his paper also says that the cultural differences matters alot since it influences both the content of the message and the way it is been expressed. Therefore, to provide an appropriate solution to climate change a cross-cultural communication is needed (Van den Pol, 2010).

O'Brien et al in their research denotes that values which is defined as interests, pleasure, likes, preferences, moral obligations, desires, wants, goals, needs, aversions, and attractions, play a significant role on how people respond to climate change action like mitigation and adaptation since it entails how people perceives the effects of climate change. In order words, how to adapt to climate change hinges on the values underlying people's perspectives on what the goals of adaptation should be (O'Brien et al., 2010). For instance, customary insight and practices as identified by Straza et al, are significant element of climate-related planning and of the reactions following climate occurrence and natural catastrophy and have a significant contribution to make since its incorporation in management planning can help to recognize how cultural components as well as religious practice and discord with versatility planning meets. In some other instances as seen in the case of Nambia above, women are kept from completely adding to climate-related planning, policy-making and execution. Although, women can be key advocate of ecological protection and climate versatility (Straza et al., 2018).

Furthermore, the use of customary insights by Research associations and western science in coping with and adapting to climate effects offer adavantages to both researchers and indigenous society (Williams et al., 2013). For instance, Analysts can benefit by procuring a better comprehension of indigenous qualities that should be obliged in adaption planning for landscape reclamation and management, customary advancement for adaptation, and local information, to supplement the technical learning base. While Indigenous societies can benefit by securing a better comprehension of environmental change, its effects and advancemnets for managing wit these effects that may lie outside of their cultures (Williams et al., 2013). Notwithstanding of all these benefits, concerns have been raised over potential unfriendly results of information exchange. Co-learning and co-generation procedures do not ensure fairness, equal standing or address control asymmetries since the natives are being welcomed to transfer customary information, often profoundly spiritual and core to third character, to take care of enormous -scale issues they cannot avoid and that are not of their creation (Williams et al., 2013).

Importance of Gender consideration in Climate Change Actions

Environmental change greatly effects those areas of the populace, in all nations, that are most dependent on natural assets for their occupation and who have minimal ability to react to natural dangers, such as dry seasons, avalanches, floods and cyclone. Women regularly face higher dangers and more difficulties from the effects of climate change in circumstances of neediness, although the majority of the world's poor are women as noted by UNFCCC (UN Climate Change, 2019). Knowing that women assume a demanding role in response to climate change due to their provincial expertise of and leadership in e.g. feasible resource administration and leading feasible practices at the family and society level, their involvement at the political level results in more responsiveness to citizen's needs, frequently expanding participation across party and ethnic lines and conveying more sustainable harmony (UN Climate Change, 2019). For instance, at the provincial level, women's involvement at the leadership level has prompted improved results of climate related projects and actions. On the contrary, if procedures or projects are executed without women's meaningful involvement, it can expand existing imbalances and diminishing viability (UN Climate Change, 2019).

This is one of the reasons why Parties to the UNFCCC have perceived the significance of including women and men equally in UNFCCC procedures and in the development and execution of national climate actions that are gender-responsive by setting up a devoted plan item under the Convention tending to issues of gender and environmental change and by incorporating all-encompassing content in the Paris Agreement (UN Climate Change, 2019). This Paris agreement produced a new fund called GCF that is to

replace the Kyoto protocol by 2020. Green Climate fund is a type of climate change finance established with the goal to mobilize climate fund to help scale-up mitigation and adaption action in developing nations on equal measure (Briefing Note on Paris Agreement V., 2016). Whereas climate finance is the exchange of funds from developed nations to the developing nations to empower them to adapt to the unavoidable effect of climate change by reducing GHG and embarking on clean energy advancement ways (Foe Briefing, 2010). The Green climate Fund is seen as an instrument that can advance gender correspondence by its structures and working strategies. In order words, an efficient gender delicate approach in the GCF will guarantee that both women and men profit from intercessions funded by the GCF through expansion of involvement, recognizing potential execution bottleneck, and upgrading the effort of the activities (Schalatek et al., 2013).

Moreover, according to United Nations climate change, women frequently demonstrate more interest for the environment, support pro-environmental actions and vote for pro-environmental leaders, their greater participation in politics and in nongovernmental organizations has resulted in environmental achievements, with multiplier impacts across all the Millennium Development Goals. Thereby calling for upholding women's involvement through legislation and policies that pledge that women will be heard and participate in decision-making (UN Climate Change, 2016). Evidences have also showed that women empowerment and advancing gender equality in the issue of climate change can render results across different sectors, including food and economic security and health. And that it will also lead to a more environmentally friendly decision making at household and national levels (IUCN, 2015). However, devoting more resources into inclusive, multilateral and multisector Climate Change Gender Action Plans can assist nations to advance comprehensive action that incorporate gender interests and expands on women's rare knowledge and viewpoints. And at the same time, ensuring equal space and resources for women and men to participate in climate change decision making and action at all levels in all nations (UNDP Bangkok Regional Hub, 2019).

Furthermore, Winnie Byanyima – Director, UNDP Gender Team – said, if climate finance is wisely administered, it can help to transform traditional gender roles and reduce inequalities. Also, failing to incorporate women and men's diverse needs and perspectives into climate change responses will further disadvantage women and decrease policies' efficiency and effectiveness (UNDP, 2011). Gate also notes that gender inclusion in climate change actions matters because upto 2016 the world majority poor are women and girls who still live in unacceptable poverty (Gates, 2016). Consequently, women and men differ in their jobs, practices and dispositions with respect to activities that could assist to relieve climate change. Research shows that, in many nations men devour more vitality than women, especially for private transport, while women are frequently incharge for majority of the family consumption choices, including in relation to sustenance, water and family vitality. Considering all these information in decision and policy making could assist accomplish a more focus, adequate, healthy and climately friendly actions (WHO, 2014).

Gender inclusion simply means as indicated by UN women, utilizing co-benefits among gender correspondence and climate activity which requires a change in perspective that puts gender interests and the voice and organization of women and girls, and men and boys, at the focal point of environmental management endeavors and ventures (UN Women, 2016). In order to accomplish such a change in perspective, it is undeniable that creating climate finance gender – responsive is fundamental to empower such a move. Likewise, to achieve an upgraded adequacy of environmental change mitigation and adaptation mediation, gender equality concerns should be mainstreamed into the whole project cycle beginning with the identification of priority mediation down to accomplishment of the environmental management targets of a given jurisdiction or substance. *Gender mainstreaming* here simply refers to

thinking differently, adjusting environmental and development mediations so that they will profit men and women evenly, and changing social, economic and institutional structures towards gender fairness and women's empowerment in environmental activity and resilience building (UN Women, 2016).

Further Research

Since the themes of the encyclopedia are about organizational knowledge and technologies, gender affects and shape both of these themes. However, there is a lack of deep and analytical discussion about how gender really shapes organizational knowledge. In order words, who are winners and losers and in what contexts? Which groups of women in what particular contexts pay higher price for being empowered in climate change management? Why is climate Finance important to the climate change gender nexus? Can be researched and analysis in the further papers.

CONCLUSION

The impacts of climate change on Islands and rural areas have a critical ramification on society, culture and gender. Social and cultural gatherings are excessively impacted by environmental Change. These bands of people assume a significant role in sharing data and ought to be consulted and incorporated in all endeavors to create climate activity. Climate finance should be available to both men and women and intended to create mutual gains, not infuriate designs of disparity. Thereby guaranteeing more positive advancement outcomes and effectively advancing gender parity and women's empowerment, as well as other related social and economic contemplations.

It is also imperative to recall that women are not only defenseless to climate impacts but also active actors of change in regard to both mitigation and adaptation. Women frequently have a solid group of awareness and ability that can be utilized in climate change mitigation, hazard minimization and adaptation procedures. Due to their responsibilities in families and societies as stewards of natural and family resources, they are in best position to add to occupation procedures adjusted to changing climate realities. Nevertheless, women frequently rely on a scope of crop varieties to oblige climate fluctuation, but perpetual temperature change will not only lessen crop assortments but also conventional medicine choices. Therefore, inclusion of culture and gender scrutiny expands the viability and proficiency of environmental change policy and program advancement and builds resilience.

KEY TERMS AND DEFINITIONS

Climate Change: Alludes to any change in climate over time, whether due to regular inconstancy or on account of human activity.

Climate Finance: Is the exchange of funds from developed nations to the developing nations to empower them to adapt to the unavoidable effect of climate change by reducing GHG and embarking on clean energy advancement ways.

Culture: According to van den pol is generally defined as a total of meanings and knowledge that human beings required to operate in a certain situation, for example, understanding of language, practices, rituals, views, values and norms, etc.

Diversity: Is broadly defined to incorporate contracts in race, gender, national inception, ethnicity, capacity, and even geographical root.

Gender: In the context of climate change is described as socially constructed norms, roles, and relations that a given society considers appropriate for men and women.

Gender Inclusion: Simply means as indicated by UN women, utilizing co-benefits among gender correspondence and climate activity which requires a change in perspective that puts gender interests and the voice and organization of women and girls, and men and boys, at the focal point of environmental management endeavors and ventures.

Gender Mainstreaming: Here simply refers to thinking differently, adjusting environmental and development mediations so that they will profit men and women evenly, and changing social, economic and institutional structures towards gender fairness and women's empowerment in environmental activity and resilience building.

Green Climate Fund: Is a type of climate change finance established with the goal to mobilize climate fund to help scale-up mitigation and adaption action in developing nations on equal measure.

Values: Which is defined as interests, pleasure, likes, preferences, moral obligations, desires, wants, goals, needs, aversions, and attractions, which play a significant role on how people respond to climate change action like mitigation and adaptation.

Gendering Information and Communication Technologies in Climate Change

Sam Wong

University College Roosevelt, The Netherlands & University of Liverpool, UK

INTRODUCTION

There has been a wide range of literature exploring the relationships between information and communication technologies (ICTs), climate change and gender. The European Union (2018) regards ICTs as a revolution for developing countries. Food and Agriculture Organization (2018) considers ICTs as ‘transformative technologies. He highlights three specific functions of ICTs in tackling climate change: monitoring and measuring the impact of climate change, raising awareness and facilitating dialogue, and fostering ‘networked governance’ (p4). UNDP (2019) also suggests that increasing access to information and education is essential for reducing the unequal vulnerability of women to climate change.

The rosy picture of using ICTs to tackle gender inequalities in climate change interventions has, however, been under strong attack. O’Donnell and Sweetman (2018) criticise ICTs for focusing too much on technical solutions, and too little on the social dimensions of the problems. Castillo et al. (2018) also warn that climate change can magnify gendered and other forms of inequalities when resources and access to goods and services become constrained in a changing climate. Rising inequalities, FAO (2018) suggests, would also intensify the impacts of climate change for all individuals and communities.

Gender can be defined as the social expectations and stereotypes of how men, women, boys and girls, should behave in society. Gender enables some groups of men, and women, to gain access to ICTs, whilst constraining others from doing so (Heeks and Ospina 2010). Variations in levels of control over ICTs, built on unequal power relationships, have tremendous impact on how poor people adapt to changing climate and respond to disasters (Wong, 2019). Understanding the dynamic interactions amongst gender, ICTs, and climate change is crucial to development policies and gender empowerment.

The objectives of this chapter are to offer a systematic review of the complex ‘ICT-climate change-gender’ nexus. Drawing on examples and case studies in developing countries, it aims to identify the gaps in literature and to explore the mechanisms by which gender influences, and is influenced by, the ICT-climate change interactions. It also intends to highlight the positive and negative gendered outcomes of mitigation, adaptation and disaster-planning policies across sectors, such as forestry, agriculture and water.

The structure of this book chapter is as follows: it will first discuss the importance of gender in understanding the interplay between climate change and ICTs. It will then highlight some proposals which attempt to increase women’s visibility in the climate change and ICT policies. After examining the pros and cons of the proposals, the chapter will conclude by offering gender-sensitive interventions that help promote digital inclusion and e-governance.

BACKGROUND

10

Rashid (2016) point out that ICTs are not a new phenomenon in developing countries. Many not-so-poor communities already have television, telephone and radio for communication and entertainment. That said, the latest ICTs, such as mobile phones, internet radios, emails, blogs and videos, are potentially interactive and participatory. With these, information can be shared faster and more efficiently between individuals and communities. They reach a wider range of audience and help develop wider networks. In light of this, Kalas and Finlay (2009) suggest these new ICT developments can improve governance by ‘empowering the poor and marginalised to raise their voice for political accountability and concrete action’ (p9).

Gender is defined as the socially constructed roles and socially learned behaviours and expectations of women and men in a particular society (World Bank 2014). Gendered relations involve difference, inequality and power, and that shapes access to, and control over, material and symbolic resources (Phan *et al.* 2019). Gendered relations are ‘contextually specific and often changing in response to altering circumstances’ (Moser 1993, 230).

Gender matters in ICT and climate change research and practice because it highlights the differential access to information. It questions fundamental questions about the nature of information - what is information, who produces information, and how information is used (Roztocki *et al.*, 2019). Onwutuebe (2019) stresses that the access to, and the use of, ICTs is gender-shaped. Gender influences how the benefits, costs and risks of ICTs are distributed between, and within, groups of women and men. For instance, in some Ugandan schools, girls are expected to be discreet and should not run like boys. Influenced by this specific gender norm, along with limited supplies of computers in school, boys race to gain access to computers and the girls are left out (UN 2002, 5). Gender also influences people to make responses to a changing climate. For example, IDS (2008) suggests that it is often men, not women, who decide what investments are made on their farms – such as investments relevant to climate adaptation – since laws and social practices enable men to have control over land, money, credit and tools.

To theorise the ‘ICT-climate change-gender’ nexus, Gurumurthy (2004), Wong and Sharp (2009) and Ospina and Heeks (2010) have offered three different conceptual frameworks. Gurumurthy compares and contrasts five different theories: Liberal, Marxist, Eco-feminist, Third World, and Culture. Wong and Sharp use the ‘agency-institution-structure’ framework to analyse how elderly women negotiate access to cutting-edge water innovations. Ospina and Heeks, in contrast, build on vulnerability and the livelihoods framework to assess the ICT-gender relationship.

This chapter draws on ideas from each of these frameworks. It puts three key climate change policies at the centre of the analysis; they are: mitigation, adaptation and disaster management. By examining the processes of implementing ICT interventions in, as well as their impact on, these three climate change policies, it analyses the role of gender in influencing men’s, and women’s, access to resources. Our analyses are based on four gender perspectives:

Process of gendered negotiation: The process explores what, and how, information is created and communicated, and how men and women understand the meanings, expectations and experiences of their gendered roles. Gendered relations are constantly negotiated and contested. They enable some groups of men and women to obtain access to information and to influence the outcomes of climate change, while denying others the facility to do so.

Gendered outcomes: Men and women experience the benefits, costs and impact of the ICT-climate change interplay differently because of their differential power positions and social capabilities. The

gendered outcomes can be positive, negative and also unpredictable. They are assessed if, and how, people's practical and strategic needs are met, and if gender inequalities are challenged or reproduced.

Feedback: The gendered outcomes of ICT-climate change interactions provide feedback to existing gender relations. They allow men and women to re-negotiate their gendered roles and expectations.

Indirect influence: Some ICT-climate change interventions make an indirect impact on gender relations. Changing income distribution between men and women, for example, can affect their decision-making power.

We are, however, aware of the limitations of focusing solely on gender in our analysis. The access to ICTs is shaped, not only by gender, but also many other factors, such as socio-economic status, income, age and geography (Selwyn, 2004). Including the class analysis helps avoid the risk of homogenizing the diverse and complex experiences of women, and men, in understanding the relationships between climate change and ICTs. We are particularly interested in the gender-class intersectionality for three reasons: firstly, gender and class are mutually enmeshed. In Pollert's words, 'there are no ungendered class relations, and conversely, there are no gendered relations without a class dimension at some level' (1996, 646). Secondly, Cleaver (2003) argues that feminist studies tend to produce unnecessary binary divisions between 'powerful men' and 'powerless women'. She suggests that, while not all men are powerful, not all women are powerless. This analysis helps explain why poor, working class men are subordinated to the control of middle-upper class women in certain circumstances. Thirdly, both gender and class affect resource allocation and utilization for mitigation and adaptation. The 'gender-class' interactions offers explanations for digital inequalities, as well as solutions to digital inclusion (Masozera *et al.* 2007, 301).

MIGITATION

The mitigation strategies focus on how ICTs help reduce CO₂ emissions. In this section, we will pay attention to two prominent mitigation policies: Clean Development Mechanism (CDM) and Reducing Emissions from Deforestation and Forest Degradation (REDD+). We will examine if, and how, gender is sidelined in the process.

CDM was set up to ensure technology transfers, from developed to developing countries, in order to limit or prevent the occurrence of climate change. CDM is the largest source of mitigation finance to developing countries. ICTs, in the form of hardware, software and information, covering a wide range of new technologies in household energy, agriculture and food processing, forest management, and water pumping in rural areas, are part of the CDM programmes (Haworth *et al.* 2018).

CDM, on the whole, has been criticised for being 'top-down' in nature. IDS (2008) suggests that existing mitigation policies are over-technical and over-scientific, and leave little room for gender-focused work (p14). The limited consultation with local communities fails to 'give women and men an opportunity to define and have power over their livelihoods' (UNDP 2010a, 2). CDM is also accused of taking an implicit assumption of gender neutrality. UNDP (2010b) suggests that 'little research has been done on the gendered impacts of the CDM, making it impossible to discern the precise degree to which current projects have impacted women and men differently' (p3). Wamukonya and Skutsch (2002) explain that technology transfer in CDM is usually directed towards men, which reproduces the gendered norms that 'men are considered the decision-makers and the eventual managers of technology' (p121). A lack of recognition of women's contribution is also reflected in the CDM governance. Of the 61 people who have served as Executive Board members, UNDP (2010b) shows that only 14 were women (p3).

Another measure to reduce CO₂ is through REDD+. Deforestation is the second most important human-induced source of greenhouse gases (GTZ 2007). Tropical deforestation annually releases 1.5 billion tonnes of CO₂ into the atmosphere, and this accounts for 17% of the total of greenhouse gas emissions (ITU and GeSI 2007). Illegal logging, overgrazing, farming encroachment, rising population pressure, and exploitation of forest products by local communities for subsistence purposes are all responsible for forest degradation and a rapid reduction of tropical forest cover.

ICTs, supporting forest management and avoiding forest degradation, play a significant role in REDD+. Geographical information systems (GIS) and remote sensing images are used to monitor the geographical changes of forest cover over time. ICTs also help examine the change in quality of forests to avoid degradation on the ground. They help acquire information, such as soil type, topography, wildlife, growth and yield, to measure the changing stock (Nsita 2010). Skutsch *et al.* (2009) also suggest that ICTs can be used to promote community participation in forest management. By providing community members with hand-held ICTs, they can help count species in their forests, thus allowing 'inexpensive and bottom up monitoring initiatives to take place' (IISD 2011, 28)

The perception of danger, associated with forest monitoring, has some gender implications for local ICT forest surveillance. Drawing on examples in Usangu, Tanzania, Cleaver (2001) suggested that people form village defence committees to protect their community resources. The youth are recruited as foot-soldiers and the elders act as advisors on tactics. While women and girls are excluded from the forest policing teams, because the tasks are seen as dangerous and physically-demanding, the full responsibilities fall on the shoulders of men and boys.

While some groups of men take up the role to protect their forests, others can collude with illegal loggers, and that undermines the prosecution efforts. Studies by Nsita (2010) show that corrupt politicians, mainly men, take bribes from forest encroachers. Driven not only by financial incentives, but also by winning votes, especially during elections, the political leaders give the illegal dealers cover, such as altering forest reserve boundaries. All these would reduce the effectiveness of the ICTs in arresting illegal loggers.

The role of women and girls in forest conservation is also mixed. They are seen as partners as well as pariahs. In their participatory research in Indonesia, Haynes *et al.* (2010) suggest that, for the sake of daily survival, girls 'choose which trees to cut when [they] go to collect the firewood either after school or during holidays' (p23). However, they also help plant trees if seeds are available. Women are encouraged to join local forest committees to get their voice heard. However, Castren and Pillai (2011) find out that women are often under-represented in the committees. Their tokenistic participation also fails to make real impact on the decision-making around forest management.

ADAPTATION

Adaptation strategies aim to increase adaptive capacity of vulnerable groups by strengthening their coping strategies to withstand, recover from, and adapt to climate change (Gumucio *et al.*, 2018). There are three main roles of ICTs in adaptation. Firstly, aerial photographs, satellite imagery and grid technology predict, identify and measure the extent of the problems of climate change (ITU 2009). Weather projections and vulnerability assessments predict climate change impact, such as rainfall patterns. Locally-specific information feeds into decision-support tools, and these inform policy-makers and local stakeholders to enable them to come up with different adaptation and production strategies. Secondly, ICTs reduce the costs of information exchange and raise awareness and facilitate dialogue. For example, IISD (2011) suggests

that the expensive running costs of GIS data systems would be reduced by networks and information-sharing (p33). Thirdly, ICTs promote community-based adaptation exchange and citizen involvement. For instance, UNDP (2011) shows that participatory sensing by mobile phones and scenario planning workshops promote community-based solutions.

There is a sense of optimism in the e-adaptation literature that ICTs could open up an opportunity for previously-marginalised groups, especially poor women, to re-negotiate their roles in their communities. IDS (2008), for example, suggests that the process of selecting heat-tolerant plants and drought-resistant animal breeds would help women farmers assert their authority in their farms (p11). Nelson *et al.* (2002) also indicates that building resilience would improve farm productivity. Increasing women's incomes would result in economic and other forms of empowerment.

Nevertheless, Resurreccion (2011) argues that many e-adaptation interventions focus too much on technical solutions to reduce the impact of climate change, and too little on 'a complex set of responses to existing climatic and non-climatic factors that contribute to people's vulnerability' (p2). Men and women may re-negotiate their roles in the process of adaptation, but Ospina and Heeks (2010) warn that the process gives 'voice to the interests of certain groups that may not be the most vulnerable' (p30). In particular, women feel more constrained from building adaptive capacities because they are deprived of 'land rights, ownership rights for the means of production, technology, finances, information and training in climate adaptation' (Bathge 2010, 5). Without control over productive resources and access to loans, credits and agricultural extension services, Olson *et al.* (2010) argue that women do not have the power to decide what changes are needed in their farms. All these constraints, IDS (2008) suggest, reduce their incentives 'to engage in environmentally sustainable farming practices and make long-term investments in land rehabilitation and soil quality' (p4).

Nelson *et al.* (2002) also warn that many adaptation practices build on women's unpaid labour. It assumes that 'rural women are predisposed to taking an environmental care-tending role' (MacGregor 2010, 8). Their e-adaptation involvement could increase their workload, without properly addressing their strategic needs. In order to juggle increasing demands, women may shift more domestic responsibilities to their daughters, and that could reproduce inter-generational inequalities and also gender inequalities in the next generation (Oxfam 2011b).

DISASTER MANAGEMENT

ICTs facilitate disaster management by offering efficient emergency communication and post-disaster coordination (Chanana-Nag and Aggarwal, 2018). Satellite-based systems capture detailed meteorological data and offer more accurate weather forecasts. On the ground level, wireless sensor networks can monitor localised weather changes and can create a database of disaster history to construct trend- and pattern-analysis (IISD 2011). Local hazard mapping and vulnerability assessments help identify individual houses and farmlands at risk and illustrate evacuation routes. Early warning systems, especially before tsunami attacks, also help reduce casualties. Furthermore, mobile phones, text messaging and real-time on-line collaboration are useful for immediate response (Hussain 2010). Rapid data gathering, during the emergency response, facilitates logistics and provides decision-making support. ICTs also allow more flexible response to post-disaster reconstruction efforts. Additionally, ICTs provide detailed maps to show the extent and the spread of the diseases and rationalise allocation of resources for disease control (Ospina and Heeks 2010). Community radios also help raise public awareness and promote public health campaigns.

The effectiveness of ICTs in disaster planning, however, depends on who has, and uses this, access to information. Radio provides a simple and effective tool to transmit information in emergency, but research by Gurumurthy (2004) shows that it is often men, rather than women, who control the access to radio. In Gurumurthy's words, 'if the household has one radio, it is most likely to be used by men. Women may not have the leisure to listen to the radio, nor may be allowed to join the men sitting outside the house listening to radio' (p5).

In their participatory gender study in Indonesia, Haynes *et al.* (2010) found out that both male and female adults have negative perceptions of girls' responses to disasters. While they praise the boys for being able to evacuate the elderly and move livestock from the affected areas, they think 'girls can't escape from disaster' because they only know how to scream (p24). As a result, boys are allocated more resources in evacuation, and girls are left more vulnerable to the effects of the disasters.

Using the big floods in Bangladesh in 1991 as an example, Rohr (2005, quoted in IDS, 2008) highlights gender biases in the early warning systems. Rohr explains that warning information was rarely communicated to women because:

'..... warning information was transmitted by men to men in public spaces, but rarely communicated to the rest of the family and, as many women are not allowed to leave the house without a male relative, they perished waiting for their relatives to return home and take them to a safe place' (p7).

Early warning systems also need to address the cultural constraints that delay the timely escape of the vulnerable. Swimming and tree climbing, for example, are useful skills to escape flash floods, but women are not taught the same skills as their male counterparts (Brody *et al.* 2008). Women's clothes in Muslim countries could reduce their mobility. Many of them were drowned because of this in the Bangladeshi flood in 1991, whereas the men could cast off their outer garments without censure.

Apart from gender, class also offers explanations for different capacities of women, and men, in mitigation, adaptation and disaster management. Low-income social groups are more vulnerable to climate change than their high-income counterparts because they tend to live in more hazardous places and have less protection. Equally, the high-income groups are more quickly to recover from losses more quickly in natural disasters since they are more capable of drawing on insurance, social safety nets and entitlement programmes (Masozera *et al.* 2007). In term of social participation, Leduc *et al.* (2010) discover that indigenous Nepalese women living in mountain have more power than their counterparts in lowland. They have greater independence and more control in making decisions. Their relatively active involvement in managing household and community resources would, therefore, have significant implications for adaptation strategy deployment. In the case study of White Volta water management in North Ghana, Wong (2016) also indicates that wives of chieftains in the trans-boundary water committee agree to build a 10 meter-wide buffer zone to make better preparation for river floods. This ambitious land policy means that poor, working class female, and male, farmers have to stop cultivation along the river banks and to move uphill to seek alternative livelihoods.

SOLUTIONS AND RECOMMENDATIONS

The previous sections have examined how gender affects the effectiveness of ICTs in mitigation, adaptation and disaster management. They have also highlighted the obstacles that constrain some groups of women, in particular, from exercising their agency in drawing on ICT resources to tackle climate change.

In addressing the gender biases, some suggestions have been mentioned in the literature in an attempt to raise the visibility and representation of vulnerable women and men. The proposals are: collecting sex-disaggregated data, stressing women-only interventions, providing women-friendly funding, and focusing on the agency of women. This section will evaluate these proposals and examine how some suggestions may not be able to achieve women's strategic needs, and worse still, may further reinforce their subordination.

Gender mainstreaming aims to integrate gender analysis into project design and public policy-making. UNDP (2008, 3) defines gender mainstreaming as:

'The process of assessing the implications for women and men of any planned action, including legislation, policies or programmes, in all areas and all levels. It is a strategy for making women's as well as men's concerns and experiences an integral dimension of the design, implementation, monitoring and evaluation of policies and programmes in all political, economic and societal spheres, so that women and men benefit equally and inequalities is not perpetrated'.

The intention of gender mainstreaming is to avoid the absence of a clear ICT strategy and policy which could affect gendered outcomes (World Bank, 2018) and to ensure that gender concerns are incorporated from the beginning and not as a corrective afterwards (Hafkin and Taggart 2001).

The main obstacle to achieving gender mainstreaming in developing countries, Etta (2005) claims, lies in a lack of a clear set of sex-aggregated data over the use of ICTs and the impact of climate change interventions. UN (2011) also suggests that a systematic gender analysis requires a good set of sex-aggregated data in order to establish gender-sensitive benchmarks and indicators to measure changes and improvement.

While data matter in social research, IDS (2008) argues that a gender- and class-sensitive approach requires more than a set of disaggregated data since it risks reinforcing fixed binary roles assigned to women and men. Instead, good quality data should reflect the 'contested, changed and reinforced' processes of gender and social inequalities (Resuureccion 2011, 7). Qualitative information, such as local power structures and control over key economic assets and social norms, is crucial to 'evaluate women's situation as compared to that of men in relation to specific environmental concerns' (Lambrou and Piana 2006, 12). In addition, Gurumurthy (2004) stresses that engendering ICTs is not simply about greater use of ICTs by women or men, but it is about 'transforming the ICT system' to meet their strategic needs (p2).

Gender disparities in ICT and climate change policies, Mittal (2016) suggests, are a result of a lack of participation of the powerless in the decision-making process. Governance strengthening is, therefore, intended to identify and overcome barriers to gender participation in decision-making. To enhance gender involvement, two key questions are raised in the literature: firstly, who participates, and secondly, how the institutions are designed.

A key question touches on whether women are targeted exclusively in the interventions or whether men should equally be considered. The women-only advocates suggest that women are generally poorer than men, and consequently, they are more vulnerable to climate change. Women compares 70% of the world's poor (MacGregor 2010). More women live in rural areas than men, and they rely on natural resources for survival, yet, their land rights are often denied (Oxfam 2011b). In addition, the literacy rate of women is lower than that of men. In Sub-Saharan Africa, for example, only 53.3% of women are literate whilst men have achieved 71.2% (UNDP 2011). To enhance female participation, gender experts and female scientists are targeted and invited to join in the preparation of climate change policies in order to 'improve dialogue between IT and gender policy makers' (Hafkin and Taggart 2001, 5). A

quota system, such as fixing the numbers of female ministries and a percentage of women activities per district, is proposed to foster women's leadership in key institutions and gender-responsive funding for action (Jolly *et al.* 2004). Another women-only group example includes women's community gardens in Malawi to ensure food security in times of flooding, and women-only self-help groups to produce organic staple crops to cope with climate change (MacGregor 2010).

Women-only interventions have, however, been criticised for homogenising women's experiences. Middle class women, for example, usually have higher access to ICTs than most poor men in rural areas (World Bank 2014). UN (2002) also suggests that single mothers, widows, disabled women, aged women and women in urban and rural areas have different identities, and their strategies to adapt to climate change can be very different. Furthermore, not all women in developing countries are low in internet use. South Africa and Chile are two examples where have achieved 50% connection. Cleaver (2003) warns that the exclusivity of women also risks considering the power relationships between men and women a 'zero-sum game'.

FUTURE RESEARCH DIRECTIONS

Men are 'gendered beings' too (MacGregor 2010). Poor men and boys are also vulnerable to climate change. Older men, for instance, are less tied into social networks than women, and that would put them at a disadvantage when they seek help from their communities (IDS 2008). Understanding masculinity also helps understand how men and boys facilitate, as well as hinder, women and girls in building resilience and using ICTs. For example, in the 'hole of the wall' computer experiment in India, Hafkin and Odame (2002) noted that: 'the aggressiveness of boys pushing away girls prevented the girls from using the computers' (p13). Additionally, the trend of digital education in developing countries benefit middle class families more than their working class counterparts because the latter is less likely to send their children to schools since they do not consider education as investment.

Despite the seeming incompatibility, the women-exclusive interventions and the proposal to include men are not mutually exclusive. In many cases, women feel more comfortable expressing their concerns in meetings, without the presence of their husbands or other men. Thus, when UNDP (2010a) conducted vulnerability assessments in Morocco, men and women were consulted separately, but the interests of men and women were equally taken into account.

Another key question concerning gender-sensitive governance is about how institutional arrangements are made. Developing a close partnership with local NGOs seems to build better governance. NGOs offer ICT training and access in their outreach strategies and climate change-related capacity building programmes (UNDP 2011). However, UN (2002) finds that many women's organisations and gender-focused groups perceive ICT policies 'an issue reserved for specialists' (p10). A genuine bottom-up approach working with local stakeholders to develop ICT capacity is rarely materialised. Although the World Bank (2017) suggests that improving governance provides an opportunity to combine modern communication systems with indigenous knowledge, Gillard *et al.* (2007) find that indigenous knowledge is often ignored or unnoticed. The 'bureaucratisation of gender guidelines' and the prescribed initiatives, they argue, do not pay adequate attention to cultural specificity of gender relationships (p6).

How to finance ICT and climate change projects has significant implications for affordability, accessibility and gender. The World Bank (2018) suggests that privatisation and liberalisation help lower user-prices of ICTs. Reforming the telecommunication sectors in developing countries and the licensing of new operators to introduce competition, the Bank argues, would ensure ICT access to the poor and

the underserved. To finance broadband infrastructure, innovative public-private partnerships are seen as catalytic vehicles to attract additional private sector investment.

To expand women's financing options, UNDP (2011) suggests improving women's access to micro-finance and other sources of credit. It also encourages the development of 'gender-sensitive climate change investment plans' which will facilitate access to financing for those most in need, particularly women and community groups (p13). In Ghana, for instance, a specific fund was set up to support initiatives that target women and promote gender equality in adaptation strategies.

UN (2002) shows scepticism of privatisation. It suggests that: 'ICT policy is frequently driven by the politics of the ICT sector, often impelled by commercial interests' (p11). Oxfam (2011a) argues that expanding financing options by micro-finance would risk imposing greater financial burden and stress on vulnerable women and men. Oxfam instead stresses the need to set up 'gender-sensitive funding guidelines' and 'equal gender representation in all decision-making bodies' (*ibid*, 3).

The agency approach focuses on 'individual capability to be and to act' (Bebbington 1999, 5) and considers access to information an act of empowerment. To challenge structural constraints, Hakfin and Taggart (2001) stress the importance of active participation amongst women. Women should make use of SMS messaging technology to develop collective networks.

While raising women's agency is crucial to challenging gender stereotypes, the understanding of the structural arrangements is equally important in promoting gender sensitivity in the ICT-climate change nexus. The denial of women's rights to land, for example, underlines the structural constraints that women face in mitigating and adapting to changing climate (Gurumurthy 2004). The social embeddedness approach, exploring the interplay between agency and structure, seems to provide a more nuanced framework in understanding the mechanisms of how gender shapes, and is shaped by, ICT and climate change interventions. Ospina and Heeks (2010) adopt a similar approach, highlighting the combination of personal preferences, social pressure and other decision-making mechanisms that influence adaptive capability and the outcomes of *achievable* and *actual* functionings (p9-10, original emphasis). Women, for example, feel constrained from using public cybercafé and rural information centres, not only because cultural norms restrict their mobility, but also because of the perception of safety and the unsuitable opening hours of the shops (Bathge 2010).

CONCLUSION

This book chapter has examined how gender shapes, and is shaped by, the ICT-climate change interactions. It has demonstrated the unequal gender and social practices that mean women and girls are more likely to be systematically disadvantaged in terms of assets, institutions and structures in the 'ICT-climate change-gender' nexus. Firstly, compared to men, women are less likely to access technology information. Deprived of land rights, they cannot make decisions about whether, and which, agriculture-related ICTs would be implemented. In addition, women struggle to make their voice heard in the mitigation policies because of their restricted access to finance.

Secondly, women are more institutionally-constrained than men. Cultural norms of behaviour shape what decisions women, and men, can take and what responsibilities they are required to take on. The exclusion of women in forest governance, for example, is related to the perceived danger to women of using ICTs to monitor illegal logging activities. Men bearing risk to protect their forests are given a legitimate voice to make decisions on behalf of women. In disaster management, rigid gender norms and cultural practices delay the evacuation of women and girls in cases of emergency. That said, on some occasions, the heroic culture amongst men and boys also put them at risk.

Thirdly, in term of social structures, women are excluded from decision-making in the policy design and resource allocations. The effectiveness of ICTs in disaster prevention is undermined by the masculine culture of information dissemination. Women are also less represented in formal decision-making bodies, such as CDM and REDD+.

In our analysis, we are aware that women, and men, are not homogeneous groups. The gendered processes and outcomes of the climate change-ICT nexus are further complicated by other social forces, such as class. According to Roehr (2007), class identities play a role in explaining people's differences in influence, attitudes and contribution to climate change (p3). Our analysis has also suggested that middle- and high-income groups have better access to ICTs and higher capabilities in managing climate change than their low-income counterparts.

To conclude, the 'ICT-climate change' interventions need to be both gender- and class-sensitive by considering the following issues:

- (1) Contextualising gender mainstreaming: gender mainstreaming is useful for integrating gender analysis into ICT policies. It acknowledges that men and women perceive and receive information differently, and that requires diverse approaches to adaptation. However, we also need to take class identities into account. Any attempt to re-position women and girls as 'eco-carers' is problematic because this fails to capture their protective, as well as their destructive, role in relation to natural resources. Without addressing the unequal power relations between mother and girls, e-adaptive practices can also help reproduce the inter-generational inequalities.
- (2) Governance strengthening: crafting new and reforming old, institutional arrangements is essential to improve gender inclusion. Women-only interventions are sometimes necessary to empower previously-excluded women to engage in ICT-related decisions. However, poor and powerless men should also have their say in climate change and ICT strategies.
- (3) Gender-sensitive funding mechanism: securing adequate funding to support ICT interventions is crucial to gender empowerment. Yet, targeting women by micro-credit projects risks putting an additional financial burden on them, and that needs serious re-consideration.
- (4) Agency-structure dynamics: women are active agents, but they are socially constrained from engaging in ICT-related decisions. Women's class identities, preferences, institutional arrangements and politics need to be taken into account in order to tackle digital exclusion.

We argue that these four suggestions are useful for development agencies, governments and NGOs to improve the gendered and classed outcomes from use of ICTs in response to climate change.

KEY TERMS AND DEFINITIONS

Adaptation: Adaptation underlines the importance to help poor communities adapt to changing climate.

Disaster Management: Disaster management touches on how climate-related disasters, such as floods and droughts, are prevented or alleviated.

Gender: Gender is defined as the socially constructed roles and socially learned behaviours and expectations of women and men in a particular society.

Gender Mainstreaming: The process of assessing the implications for women and men of any planned action, including legislation, policies or programmes, in all areas and all levels.

Information and Communication Technology: ICTs include television, telephone, radio, mobile phones, internet radios, emails, blogs, and videos for communication, entertainment, activism and control.

Mitigation: Mitigation focuses on the processes to reduce CO₂ emissions.

Poverty: It does not simply mean a lack of money, but it also focuses on empowerment, autonomy, and dignity.

World Bank: Named as the International Bank for Reconstruction and Development, the World Bank was set up in 1945 with the aim of promoting the post-Second World War reconstruction. It has since evolved and become strongly focused on worldwide poverty alleviation.

Section 11

Ethics and Responsibility

Science and the Morality of Weapons Research

John Forge

University of Sydney, Australia

INTRODUCTION

If it were not for *weapons research*, there would be no predator drones or smart bombs or improvised explosive devices or assault rifles. The insurgents in the Middle East and elsewhere would have no means to fight, and there would be no wars, large or small. Even more importantly, there would be no vast arsenals of thermonuclear weapons capable of ending much of the sentient life on the planet. The world would then most certainly be a safer place. But weapons research is not something new: the gunpowder weaponry of the early modern period was the product of research, as were the torsion catapults in Greece at the time of Philip and Alexander of Macedon. Whatever else is true about weapons research, it is clear that it introduces new (or improved) means of killing and destruction, and this is sufficient to define the activity. For instance Forge has given the following, generally accepted, definition: Weapons research is research carried out with the *intention* of designing new weapons, or improving the design of existing weapons, or designing or improving the means for carrying out activities associated with the use of weapons (Forge, 2013: 14., emphasis added). Weapons research would appear to be a very weighty matter, something that one might imagine philosophers, and others who think about such things, would have had a lot to say; surprisingly, not much at all has been written on the subject, though some explanation of this neglect will be given in this chapter.

The main issue for *ethics* and weapons research centres on the ethical or moral evaluation of the activity: Is it *ever* morally justified to design the means to kill, harm and destroy, and if so, under precisely what circumstances? Turning to science and its relation to weapons research, the question here is the *role* that science plays in weapons research. Perhaps weapons research is a wholly (applied) scientific endeavour or perhaps science is a part of weapons research? Bringing ethics back in, if weapons research is deemed morally wrong, then is it the case that *whatever* role science plays is also wrong? To talk about science playing a role here means in practice that it is scientists, people, who are undertaking actions that appear morally suspect. To answer these questions, four examples will be given which will clarify the roles that science can play in weapons research. For instance, if weapons research itself is understood as applied science, as it is by Arrigo for instance (Arrigo 2000: 303), then one might expect this to entail the application of theory to the design for new weapons, for true or radical innovation.

There are other ways in which science can inform weapons research, as will be seen presently. The first of the three examples show how science, both as theory and as method, can directly inform weapons research in the sense that the intention of the work in question was to produce new or improved weapons. The fourth example is different. It concerns *dual use* research, work that is not motivated by the desire to produce weapons but nevertheless provides a basis for doing so. This is an issue of current concern, so is worth discussing here. Before moving on to these examples, some general, and very brief, comments about ethics and the way it can apply to an intellectual activity such as science are in order.

DOI: 10.4018/978-1-7998-3479-3.ch097

This is appropriate because it cannot be assumed that the audience for the present topic is familiar with philosophy or ethics; but it is necessary to have a framework.¹

BACKGROUND

A straightforward way to describe ethics is to say that it is a study which deals with what persons ought and ought not to do. It is thus to do with the choices, actions and behaviour of mature competent people. Some of the things that people do do not affect others, other humans, other sentient beings, in any significant way and hence these do not come under the purview of ethics. Those actions that do affect others are, however, open to moral or ethical evaluation: are they right or are they wrong? To resolve that question, one needs to appeal to a moral system. All such systems forbid certain actions, namely those that inflict unjustified harm on others. This is surely intuitive and obvious: *no one* wants to be harmed. It is almost by definition that no sentient being wants to feel pain – assuming that the pain does not indicate that some medical treatment is working or some such – and to be in pain is one form of being harmed.

Some moral systems require people not only to refrain from harming others but also to provide some positive benefit for them. Jeremy Bentham and John Stuart Mill, the nineteenth century English philosophers, famously believed that one ought to strive to increase the amount of happiness in the world. However, morality is supposed to be *impartial* in the sense that it forbids discrimination in regard to moral action. Prohibitions on harming do not end with family or friends or community or country: *nobody* should be harmed, no one at all. Some critics of the style of morality advocated by Bentham and Mill have pointed out that it is impossible to increase the amount of happiness in the world impartially: no one can make everyone happy! Just how serious this objection is is a matter of ongoing debate. But it is only necessary here to note that this kind of moral system shares the prohibition on harming with the former kind: for the topic at hand, it is clear that the moral evaluation of weapons research, whatever else it might involve, will not be such as to see it as an activity which aims to increase the amount of happiness in the world.

When a person does something that contravenes the dictates of morality, they are guilty of moral wrongdoing. If one person harms another, then this is obviously a bad thing from the perspective of the victim, but what of the agent, is it also somehow bad for her? The short answer is that it is bad for the agent, in the sense that performing immoral acts attracts the disapprobation and distrust of others, although this is not an easy idea to explain when space is limited, as it is here (see Forge 2008: 92-93) And we also need to ask if all actions that harm attract such moral censure or only those that are intentional. All intentional acts are such that the agent foresees the outcome, assuming that matters do turn out the way they were planned, but not all foreseen outcomes are intended. A dentist who drills her patient's tooth foresees that it will hurt, and in the sense harm the patient, but she intends to save the tooth not cause harm. This raises the issue of the justification of actions that knowingly but unintentionally cause harm. Some such action can be justified, but others cannot, as is the case for dual use research.

Most philosophers do not believe that the rules of morality are absolute and cannot be broken in any circumstances. For example, most accept that a moral rule such as “Do not cause pain” has justified exceptions. Clearly, a dentist who inflicts pain on her patient to save his teeth has not done something morally wrong – provided that the patient understands and assents to the treatment. Also, it is generally agreed that it is permissible to cause pain in self-defence, if that is the only way to defend oneself. This leads to the view that *justifiable* exceptions to the overall moral prohibition against harming will be such as to show that the harm inflicted will prevent other harms. Just how this is worked out will vary from

case to case, and it is here that much of the hard work in ethical reflection and evaluation takes place. One might think as a basic principle that the harms prevented should be at least as much or many or as great as the harms caused if there is to be justification, and that therefore it must be necessary to be able to make some informed assessment of what these might be. This brings the discussion back to weapons research, an activity that aims to provide the *means* to harm. It is now necessary to look at some examples.

Solutions and Recommendations

Examples of Weapons Research

1. It is well-known that both kinds of nuclear weapon, fission and fusion weapons, were the *direct results* of the application of scientific theory to design. Without advances in nuclear physics in the 1930s and 1940s, the very idea of a nuclear weapon would not have been dreamed up. Rhodes gives an excellent account of the genesis of the idea of a fission weapon, from the speculations of Szilard from 1933 to his work with Fermi in the US, and the ‘memorandum’ written by the émigré scientists Frisch and Peierls in England which made predictions about crucial nuclear parameters. The designs of the two kinds of fission bombs made during the Second World War were determined by the properties of the fissile materials used, matters that were uncovered by painstaking research.² The idea for a thermonuclear weapon emerged from the atomic bomb project, and was also driven by science and by scientists. Indeed, the fusion reactions that power these weapons must be initiated by ‘fission triggers’, so not only did the research into fission or atomic bombs lead to thermonuclear weapons, the products of the former were integral elements of the latter.³

The research leading to nuclear weapons was exceptional in that scientists, including all of those mentioned above, took the initiative in agitating for programmes to investigate the possibility of using the recently discovered fissile materials for a weapon of terrible destruction, to the subsequent regret of some of them. The military is now well-aware of the power of science and has set up agencies to oversee the application of scientific theory to the design of new weapons systems. The best-known is the US’s Defense Advanced Research Projects Agency, or DARPA; notice that, in common with armed forces the world over, the word “defense” appears in its name. There are equivalents in Russia, China, the UK, France, Israel and other countries.

2. In the nineteenth century the weapons that caused the majority of fatalities and injuries in war, artillery and the infantryman’s longarm, were transformed by the scientific analysis of existing armaments. Smoothbore cannon and muskets were transformed into steel, breech-loading guns whose recoil was damped and rifles firing clips of cartridges using smokeless powder.⁴ These are instances of science *improving* existing designs. One example will be given as an illustration.

All smoothbore weapons which fire balls, musket and cannon balls, are inherently inaccurate because of uncontrollable forces which act on balls as they spin in the air after leaving a gun barrel. This is called the Magnus Effect or Magnus Force, after the German physicist Heinrich Magnus who described it in 1852. It was also investigated by the English physicist Benjamin Robbins, in his book *The New Principles of Gunnery*, published a century before Magnus’ work (Steele 1994: 359). The effect is this: unless a ball only spins about the axis in the direction it is travelling, what is called the roll axis in aeronautics, it will experience unequal pressure on either side in the direction of its motion, and hence be deflected in the

direction of the axis of spin. In other words, it will not travel straight, and if it actually hits (anywhere near) its target, then this is a matter of luck.

This analysis showed that if only the bullet could be made to spin about the roll axis, accuracy would be greatly increased. The first attempts to do so involved ‘rifling’ musket barrels, fitting them with raised ‘lands’ spiralling down the inside of the barrel which caused the ball to spin about the required axis. There were two problems: the rifled musket was very slow to load because the ball had to be hammered down the barrel, and the barrel became fouled after only a few shots because the powder residue collected around the lands. These problems were solved by three innovations. There were, in the first place, advances in metal working that allowed relatively efficient breech-loading rifles – leakage of gas from around the breech was eventually dealt with by gunsmiths such as Paul Mauser. Then there was progressive improvement in propellant until eventually smoke-less powder became available. Finally, bullets were designed that would not stick in the barrel on the lands. The idea was that the bullet would have two parts; a base that was made out of a relatively soft material that would deform in the lands and impart a twist to a hard core made narrower than the base so that it would not stick in the barrel. After two attempts in England in the 1820s, eventually a French innovation by Captain Claude-Étienne Minié of the French Chasseurs was successful in 1847.⁵ This led to many orders of magnitudes increase in lethality: in the American Civil War over half a million casualties, including two hundred thousand killed, were caused by ‘Minié rifles’.

3. The application of scientific theory, either to produce quite new weapon designs or to improve existing ones, is a relatively new phenomena, beginning with the study of -ballistics in the seventeenth century (see Hall 2009). However, *systematic* research into weapons design took place at least as far back as the fourth century BCE. Remarkable work was done in that century in relation to the design of the torsion catapult, which marked the beginning of effective siege artillery. A torsion catapult works because of the restoring force exerted by ‘springy’ material, like rope, which has been stretched. Wrapping rope around a stout piece of wood fixed to a frame, embedding a handle in the mass of rope and then pulling the handle back will create a torque: the handle will fly back to its resting position when released. It can be therefore seen how, in principle, such a device can be used to cast stones when placed in a basket attached to the handle.

It is not known how the Greek engineers discovered the torsion principle and applied it to designing catapults, but this must have been done *empirically* as the theory was not formulated until much later. However, the design of torsion catapults was codified in treatises which gave general instructions how to build them. These instructions were general because formulae, known as the hole formulae, gave the key parameter for casting stones of a given weight or arrows of a given length. The Greek engineers had discovered formulae that related the optimal size of the hole in the catapult frame in which the wood about which the rope or springs was to be wound to the weight of the stone or length of the arrow. The former is more complex and involves a cube root, which gives an equation that Greek mathematics at the time could not solve exactly. Perhaps still more remarkably, the treatises gave approximation methods for solving the equations in question.⁶

Dual Use

4. To introduce this example it is necessary to begin with some words about the idea of dual use. To begin, three different categories of dual use items can be distinguished: research, technologies and

artefacts. These are clearly different sorts of things. Research is an activity, while technology is a form of knowledge, knowledge of the techniques for the production of artefacts, whereas artefacts are objects. Certain instances of these kinds are classed as dual use because they can have both a 'good' and 'bad' use. Ammonium nitrate, for example, is normally used as a fertilizer, but it can also be used to make so-called fertilizer bombs.⁷ The dual use categories are related: research aims to give us technology, which in turn produces artefacts. It is the latter that normally has the immediate impact on the individual, be this good or bad. Forge's suggested definition of a dual use item is as follows:

An item (knowledge, technology, artefact) is dual use if there is a (sufficiently high) risk that it can be used to design or produce a weapon, or if there is a (sufficiently great) threat that it can be used as an improvised weapon, where in neither case is weapons development the intended purpose. (Forge 2010: 117)

Threats differ from risks here in that they signify the intention to do something harmful, rather than the possibility that something harmful might happen. Risk is coupled here with the design of (new) weapons but threats with improvised weapons. States threaten one another, as Iran and Syria are doing at present, though the threat here is usually conditional. However, in regard to dual use, one is more concerned at the moment with sub-state actors, such as terrorist organisations, using or adapting existing items for improvised weapons, as has been done with ammonium nitrate, than with states arming themselves with improvised weapons, as states do not usually need to improvise weaponry.

There have been a number of issues about dual use that have been discussed in the literature, but what is of interest here is whether undertaking dual use research is itself morally wrong, or whether it is morally permissible – deliberately taking advantage of dual use research and developing weapons is morally wrong. The example to be used here has to do with the possibility of using dual use research to develop nuclear weapons. Recall that naturally occurring uranium comes in two isotopes: chemically identical species of atom that have different physical properties owing to the presence of differing numbers of neutrons. In the case of uranium, the lesser abundant U-235 is much more fissile, much more apt to fission and release energy, than the more abundant U-238. A sample of uranium metal is said to be enriched if the amount of U-235 is greater than 0.7%, which is the proportion found in nature. The greater the enrichment, the greater the neutron flux, the greater the flow of neutrons in the metal. It is possible in theory to make a nuclear weapon with uranium enriched to a little less than 20% but the accepted practical limit is set at 20%, what is referred to as highly enriched uranium or HEU, when 30 kg of the metal would be needed (Glaser 2017:8). By contrast, only 2.3 kg of 95% enriched uranium is needed for the same purpose – uranium enriched to 90% or greater is known as military or weapons grade. Civilian power reactors, on the other hand, only require enrichment to about 4%. A civilian power reactor fuel rod is therefore not itself a dual use item because it cannot be used to make a bomb, unless subject to further enrichment. Weapons grade uranium is not suitable for power reactors because the extremely high neutron flux that makes bomb making easy but cooling very difficult, so it is not itself a dual use item either. However, there is another sort of reactor, the research reactor, which does require HEU, and hence a sample of HEU is dual a use artefact: it can be used for research or bombs.⁸ The question then is whether a research project aimed at producing uranium enriched above 20%, but below weapons grade, designed for a research reaction is morally permissible, when there exists the possibility of the technology being used to produce the fuel for nuclear weapons.

Analysis and Discussion

11

If weapons research is morally wrong, then it would appear that the actions of any scientist who contributes to weapons research are also morally wrong. But the matter is not quite so straightforward. A scientist who knowingly, willingly and intentionally engages in weapons research is as open to moral censure as any other weapons researcher, assuming that weapons research is a proscribed activity. It is not so clear, however, that a scientist who does not intend that her work be used to further the ends of weapons research, but sees that it may well in fact do so is also blameworthy. It is less clear still that a scientist who does not foresee this outcome, assuming it comes about, is to blame. It would not be necessary to address any of these issues if weapons research was not morally wrong, so this matter must now be discussed.

It was mentioned above that the topic has received much less attention than it deserves.⁹ Forge, who has addressed the topic at some length and argued that weapons research is morally wrong under all circumstances, believes that the question of the morality of weapons research has been assimilated to questions about the justness of war, about which a great deal has been written of late, and he believes this is a mistake (Forge 2013: ix)). The consensus about war is that war is just or morally permissible – no blame attaches – if it resists aggression. This is the ‘modern view’ which sees just war as more than self-defence, other defence being allowed if the other is the victim of aggression. The implicit corollary is that measures such as weapons research are justified if they aid in the prosecution of a just war or in the pursuit of self-defence or deterrence.¹⁰ This is the standard rationale or *standard justification* of weapons research. Forge denies that this justification is convincing. However, Kemp, one of the few who have discussed the ethics of weapons research, claims that it is not only permissible to undertake weapons research for defence, and maintains that it is a *civic duty* imposed on scientists to do so (Kemp 1994). Forge and Kemp therefore adopt diametrically opposed viewpoints, and the topic can be explored by comparing and assessing their respective positions.

Kemp claims that since the state has a duty to protect its citizens, and since Hobbes many political philosophers believe that this is the *raison d’être* of the state, then those who are able to assist in this vital endeavour by designing the means for defence have a duty to do so. Note that a civic duty in this sense is not a *moral* duty, as it only applies to a part of the moral community, namely one’s fellow citizens, and hence lacks the (completely) impartial character of morality. Expressed in these terms, Forge’s view is that it is moral duty *not* to undertake weapons research. Forge does not deny that states have a right to defend themselves, or defend others from aggression, nor does he deny that weapons research can help to achieve these ends. What he does deny is that this is *all* that weapons research does, namely provide the means to resist aggression, whatever the intent behind it. Note also that Kemp’s position is compatible with weapons research being permissible while Forge’s is not. Which is correct? Kemp’s view seems to be convincing, but when weapons research is analysed in more depth, this initial reaction is seen to be wrong.

Hacking maintains that what weapons research produces in the first instance is *knowledge*, instructions for making new or improved weapons, not hardware (Hacking 1986).¹¹ Weapons research is not the same thing as weapons manufacture. A scientist who successfully discharges her civic duty does not therefore provide a *unique* array of defensive weapons for her country, but a *design*, and any institution with the requisite skills and resources could produce identical weapons if it possesses the design. For instance, the Kalashnikov, the AK-47, the most widely made weapon of all time, has been manufactured from 1947 by the Soviet Union, Russia, Poland, Hungary, East Germany, Bulgaria, Romania, China, North Korea, Yugoslavia, Iraq, Egypt and India, and variants by Finland, Israel and South Africa.¹² Mikhail

Kalashnikov invented a highly effective assault rifle, but should he be praised for discharging his civic duty or condemned for introducing into the world a terrible new means to kill? Clearly, his innovation spread beyond his own country. Successful weapons tend to become ubiquitous. Both sides in the American Civil War used ‘Minié rifles’, as did both sides in the Franco-Prussian War of 1871. By the First World War, all protagonists had machine guns, quick-firing artillery as well as reliable rifles. There was less uniformity in the armaments of the Second World War, though all sides had tanks, bombers, fighters, field artillery and so forth, and there is still less uniformity today. This trend is due to the vastly increased pace of weapons research and it is to be expected that states will strive to copy successful weapons innovations as much as they can. This may not be easy and it may not always be clear how it can be done, but the very fact that many different countries come up with weapons that are remarkable similar shows that it happens. Weapons innovation cannot be contained.

If successful weapons innovation does not lead to a unique array of weapons, perhaps this does not matter if leads to weapons that can *only* be used to defend against aggression – perhaps Kemp’s position can be resurrected along the lines that designing defensive weapons is a civic duty? The role of a defensive weapon, or weapon that is postured defensively, is to actively protect an asset, but this does not necessarily amount to defending against aggression. The work of Luttwak on the levels of strategy shows the relationship between defence and its strict ‘opposite’ offence is complex and multi-faceted.¹³ One implication of Luttwak’s analysis is that a state that would embark on a war of aggression needs a range of defensive options. It needs to be able to defend itself, its ‘homeland’, from retaliation, it needs to defend captured territory and its forces in enemy territory from counter-attack, etc. Thus, if the overall theatre or grand strategy is one of aggression, with the long-term goal of capturing territory or otherwise exerting hegemony, at ‘lower’ levels defensive tactics and even defensive operations may be necessary at certain times and places, and conversely. Fighting on the Eastern Front in the Second World War, after Hitler invaded the Soviet Union, exemplified this dynamic. At the level of grand strategy, Hitler was waging an aggressive war of conquest, while Stalin was defending. But even as early as the third month of the war, the Germans were mostly on the defensive, with their infantry holding positions while their tanks, the main instrument of the blitzkrieg operations, were being repaired and refitted.¹⁴ Thereafter, the German offensive re-commenced, stalling finally in November 1941 in front of Moscow, and the next two years the protagonists defended and attacked one another in turn until the Soviet Union began to prevail. All the weapons both sides had at their disposal were used in all forms of fighting, including tanks that were deployed in mobile defence: there were no weapons *only* used for defence. Kemp’s position therefore cannot be salvaged.

FUTURE DIRECTIONS

Forge maintains that since weapons are, by their very nature, the means to harm, then research which aims to introduce new or improved weapons into the world requires justification, and that the only possible justification is that the weapon in question will prevent more harm than would be the case were it not available.¹⁵ This kind of justification lies behind all references to defence in relation to weapons research, military spending and so forth. But this demand cannot be satisfied: weapons research produces knowledge in the form of designs which can be implemented in the future in circumstances that are unknowable – as the examples discussed above have shown - and since there is no such thing as a weapon that cannot be used to aid aggression, there can be no assurance that an episode of weapons research will produce a weapon that prevents more harm than it causes. It is precisely this assurance that is needed if

weapons research is to be justified, hence Forge argues that weapons research is always unjustified. The historical record shows that wars have become more frequent and more deadly since scientific advances began to be applied systematically to weapons research, and so the facts seem to support Forge's position. But these important issues surely need more discussion, not just from philosophers and others who reflect on weapons research, but from the scientists and other experts who actually take part. Everyone would surely hope that the very rapid pace of arms production and sales will decrease in the future and that the realisation that it is in fact wrong to design new kinds of weapons would become more apparent.

Turning finally to dual use research, how should one evaluate such an endeavour? This issue is of current concern and of ongoing discussion, but the following position will be put forward here. If research can lead to bad uses, namely to the development of new weapons, as well as good ones, how does one balance the good against the bad and what does one make of claims to the effect that if a researcher only intends the good use in a given case, then her participation is justified? The position suggested here is that the good cannot 'outweigh' the bad use and that participation is therefore not justifiable whatever the intention of the researcher. Turning to the second matter first, if an agent foresees that her actions will lead to a given outcome, then she may still be held responsible for any harmful effects of those actions even if she intended some other outcome. Not only this, but if an agent was in a position to see that her actions could have harmful effects, then she may be held responsible for these even if she did not actually foresee them – these issues are discussed in detail in Forge 2008. So when it comes to dual use, the fact that a researcher does not intend the 'bad use' which her work enables does not mean that she is not accountable for it.

When it comes to balancing good uses with bad ones, the issue involves the responsibilities of the researcher and this can be expressed as follows: How are the responsibilities of participants in dual use research to be compared to one another, in such a way that a decision can be made about whether undertaking such research is morally permissible? The position which is put forward here for future discussion is this: All researchers are obliged not to undertake work that has, or risks having, harmful consequences; this much has been agreed already. There is, however, no corresponding obligation to undertake research that has positive or beneficial outcomes. There is therefore an *asymmetry* between the responsibilities of researchers. Thus, in the context of dual use research, there is on the one hand an obligation that derives from the 'bad use, not to undertake the research, but no corresponding obligation in favour of doing the work that derives from the 'good use'. It follows that moral persons should not undertake dual use research. This position is not the last word on the question. Future work on devising a way to support the idea that there is in fact a responsibility to undertake dual use research with a view to achieving the 'good use' is one such direction.

CONCLUSION

Returning to focus again explicitly to the role of scientists, if weapons research is morally wrong and without justification, then scientists, just like everyone else, should not take part. A scientist who knowingly and deliberately takes part in an activity that is morally wrong is as blameworthy as any other participant. However, there are different ways in which scientists can be said to participate. For instance, a scientist can receive a grant from the military even though she does not intend to undertake weapons research and does not see how her work might provide a basis for weapons research. But, the military only sponsors research it thinks might be useful for its own ends, including weapons research, and this is a good reason why scientist should not accept such funding. It is also possible that a scientist knows

she is conducting research that could have military application without being sponsored by the military. This happened in the late 1930s when some members at least among the scientific community believed that current advances in nuclear physics could contribute to a weapon of mass destruction. The majority of scientists working at the time, including Hahn and Strassman, the discoverers of nuclear fission, saw themselves as ‘pure’ research scientists. Szilard sought a moratorium on publishing papers on nuclear physics in order to try to prevent such nuclear weapons research, with limited success (Rose 1998; 92). This, as well as the topic of dual use, raises complex questions about the responsibility of scientists for applications of their work that they do not intend, or even foresee, but these are questions beyond the scope of this chapter.

² See especially Rhodes 1986; for his discussion of Szilard, see 28-30, and for the Frisch-Peirels Memorandum see 321-325. Weart edited Szilard's papers, which were published in 1978, see Weart and Szilard 1978. Grandy has a more objective account of Szilard's contribution. Forge 2008 Chapter 8 is a short accessible overview of the Manhattan Project and the events leading up to it. For a more technical discussion, see Hodderon *et al.* 1993.

³ Rhodes' second book, Rhodes 1995, takes up where his first book ends, at the conclusion of the Second World War, and begins with a discussion of the Soviet atomic bomb project and moves on to the decision by the US to then proceed with thermonuclear weapons. Both books are important because they give background to the decisions to actually go ahead with the respective nuclear weapons research programmes, surely among the most momentous decisions of all time. For more on the decision to proceed with thermonuclear weapons research by one who was actually involved, see Acheson 1969, especially 344-349.

⁴ It was necessary to develop special steels for guns that used the new high explosives, both of which were due to advances in chemistry in the nineteenth century, see Manchester 2003. Manchester's book gives an excellent account of Krupps, the famous, or notorious, weapons manufacturer and innovator. Warren 1989 tells the story of George Armstrong, the English equivalent of Alfred Krupp. The problem of recoil, which had plagued gunners from the very beginnings of artillery, was solved at the end of the century by the French, see Zabecki 2004.

⁵ See Greener 1910: 629-632 for the two British attempts. An excellent account of Minié is in Hall 1997: 135-147. Walter 1979 is a comprehensive account of the nineteenth century German rifle innovation, especially in regard to the Mauser.

⁶ Marsden wrote two important books on this topic, which have become classics. One gives the historical development of Greek and Roman artillery, while the second reproduces four technical treatises, from the fourth century BCE to the first century CE, which give instructions for building catapults. Rihill is a more up to date, and perhaps more readable, general text on the topic, which does not always agree with Marsden.

⁷ Ammonium nitrate is strictly speaking a substance not an artefact because it does occur naturally: I am assuming here that it has been manufactured and is in that sense an artefact.

⁸ See National Academies of Sciences, Engineering and Medicine (2016) Chapter 3 for civilian research uses of HEU. As the title of this publication, *Reducing the Use of Highly Enriched Uranium in Civilian Research Reactors*, implies, there are moves to try to reduce or eliminate HEU in research reactors.

- ⁹ Sarah Bridger's recently published *Scientists at War: The Ethics of Cold War Weapons Research* has, in spite of the title, almost nothing in it about ethics. It is however an excellent account of the attitudes of many of the leading US weapons researchers between the launching of Sputnik and Star Wars, with special reference to weapons research and the Vietnam War.
- ¹⁰ Some Just War Theorists, and some others, have argued that certain classes of weapons, especially weapons of mass destruction, are immoral but have not (even) gone on to state the corollary to that proposition that the weapons research that aims to produce weapons of mass destruction is immoral. Fotion, Fotion 1990, gives one of the best discussion of the issue from this restricted viewpoint.
- ¹¹ This knowledge, in the form of designs, can be more or less well articulated, from the most basic and sketchy idea – for instance, using a chain reaction in a uranium assembly – to an engineering specification that could, in principle, be implemented entirely by machine. For more on this issue, see Stankiewicz 2000.
- ¹² For Kalashnikov's story in his own words, which must be taken with a grain of salt, see Kalashnikov 2006. For more details, and more objectivity, see Kanaher 2007.
- ¹³ Luttwak 1987 is the main source. But see also Liddell Hart 1973 for various ideas about what could count as a defensive weapon.

Aalborg University, Denmark

INTRODUCTION

Every action or inaction performed by a human being is as a result of a rational process. This is a process that occurs, in some cases, in a manner of seconds. In organizations, it might take a longer time. However, whatever is the case, in the process of rationality involves the weighing of factors, making a decision and mobilizing to make that decision. Ultimately, what is being mobilized are resources. These could be tangible (including human resources) or intangible resources. However, the most common resource mobilized to perform an action is human resources. This is evident in individuals, communities and organization. However, as times change and we move into the age of automation, more machines will be mobilized than humans. Nevertheless, in this chapter, the focus will be in the mobilization of human resources in a broader sense.

The mobilization of human resources to perform defined and collective action is as old as the existence of humans. The mobilization of humans is existent in organizations, societies and families. Furthermore, mobilization is not a spontaneous act even though it might occur in seconds. Rather, there are rational factors that trigger the desire to mobilize. However, understanding what makes us humans mobilize is rarely treated as a subject in literature. There are different studies on behavioral tendencies of humans and in some of these theories, triggers to taking certain actions are identified. However, these are contextual studies and not a generalized theory that actually explains what goes into the process of organizing. As a result, managers, innovators and visionaries have to rely on their guts and inborn talent to attempt to mobilize others to perform a certain action. In most cases, because of ignorance of how to go about the process, their visions and ideas remain dormant. Hence, it is necessary to understand the factors that ought to be in place before mobilization occurs and furthermore it is necessary to understand the circumstances by which another human will submit to being mobilized without coercion. Hence, the guiding question in this chapter is when and why do we decide to mobilize? Furthermore, what are the factors that trigger the decision within us to mobilize humans to perform an action?

In responding to this question, the author will extend the work on his Ph.D. thesis by combining a set of hypothesis (models) from that thesis with social theories to theories, why we decide to mobilize. Due to the word limitation in this chapter, reference will be made to the thesis. The models from the thesis are called the Community Broadband Network Mobilization (CBNM) Models (Williams, 2016). These models, though not developed to explain mobilization, has a clue on why mobilization occurs. The theories used will be Social movement theories, Logic of collective action and the Actor network Theory. The theorization involved a deductive and an inductive process. The resulting theory was the Mobilization-decision theory. This theory provides an explanation on why humans mobilize. The theory as will be explained in the chapter is useful both to individuals, organizations, communities etc.

DOI: 10.4018/978-1-7998-3479-3.ch098

This chapter consists of 7 sections. Section 2 is a review on the theories of mobilization. Section 3 presents and explains the CBNM models. Section 4 highlights the transition from CBNM models to Mobilization decision theory. Section 5 highlights the theoretical and practical implications of the Mobilization-decision theory. Section 6 highlights the future research direction. Section 7 is the conclusion.

BACKGROUND 1 - A REVIEW THEORIES WITH CLUES TO MOBILIZATION

There are different theories that identify mobilization as a conceptual process that results in an action. Most of these social theories that explain and analyze social movements (Peterson, 1989). However, social theories that investigate the concept of mobilization are rare. As a result, questions as to why and how mobilization occurs are often left unanswered. Answers to these questions can be induced from social theories. This is because these theories explain and analyze collective behavior. These theories also provide explanations for “*why social movements emerge*” (Peterson, 1989). There are other theories one can rely on. However, in this section, the supporting theories of from which the answers will be deduced are the Actor Network Theory (ANT), and the Logic of collective behavior. The community mobilization approach was considered but later, dropped. This was because ANT and the social movement theories seemed to hold the key to explaining community mobilization. The ANT provides clues as to why and how mobilization could occur and the Logic of collective behavior because it presents a clue on people or groups allow themselves to be mobilized (Olson, 1971).

The Logic of Collective Action and Reasons for Mobilization

The logic of collective action by Olsen (Olson, 1971) is one of the theories of collective action. This theory does not explain why mobilization occurs. However, it does expose what motivates individuals to be part of a large group. The theory indicates that in the exception of the existence of an incentive or coercion, individuals in large groups serve self-interests rather than the interest of the group (ibid). In other words, if the individual is not coerced, they are part of the group because of the perceived value they will derive within the group. This value is domicile in the incentives that exist in the group.

Although Olsen argues that individualism is minimized in small groups as compared to large groups, it could still be induced that the individual agents that signed up to become a part of a small group are also driven by incentives which highlights the perceived value evident in joining the group. Hence, from this theory the role of incentives, such as perceived value is highlighted.

Social Movement Theory and Reasons for Mobilization

Social Movement theories are human-centric theories. However, although mobilization is implied in the social movement theories, reasons as to why mobilization could occur can be deduced from these theories. In order to understand the Social movement theory, one has to understand the concept of social movement. Social movement is a concept with different definitions (Mario, 1992). For example, Mario 1992 indicates that social movements can be identified as a “network of informal interactions between a plurality of individuals, groups and/or organizations, engaged in a political or cultural conflict, on the basis of a shared collective identity”. Mario’s classification, though revealing, tends to limit social movements to being political and cultural in nature. This could be that most research into social movements were on political and cultural conflicts such as the civil rights movement, the women’s right movement,

anti-colonial movement etc. (examples (Sen & Ömer, 2016) (Taylor, 1989) (Meyer & Tarrow, 1998). However, other authors also identify the economic aspects as well (See example (Sen & Ömer, 2016)).

However, social movements are triggered by social problems that resulting from dissatisfaction (see (Andrée, Clark, Levkoe, & Lowitt, 2019)). Different social theories point to different sources of dissatisfaction. These sources of dissatisfaction could hold the clue as to why mobilization takes place. A social movement theory such as the deprivation theory points to the dissatisfaction resulting from the *deprivation of societal resources* to a certain portion of the population (see example (Asingo, 2017)). Another theory, the mass-society theory point to dissatisfaction arising from the feeling of being marginalized by society (see (Berdayes, 2018) (Buechler, 2013)). Furthermore, societal changes caused by deprivation and marginalization, experienced by certain class of people in society, among other factors could result in the challenge of the social structure of the society resulting in a structural strain within that society. The structural-strain theory points to dissatisfaction arising from the discontent in the functioning and structure of an organized society (Smelser, 1963) (Langa & Benski, 2018) (Nulman & Schlembech, 2017). These dissatisfactions indicates the commonality of problems. This implies that if a group of persons identifies “common problems” that could possibly result in mobilization.

However, dissatisfaction or common problems are not the only precursors to mobilization. The social movement theories, such as the Value Added Theory, indicates that mobilization will become possible if individuals can identify the value that can be derived as being part of the group. The value oriented belief could for example be triggered by structural strain (Smelser, 1963), or perceived opportunity to advance individual interest (Weeber & Rodeheaver, 2005).

Hence perceived value is once again identified either as an incentive to mobilize or to be mobilized. Another precursor to mobilize is the potential to mobilize and utilize resources. This is explained by the Resource Mobilization Theories (McCarthy & Mayer, 1977). Another factor is on how social actors create and conceptualize the ideas either resulting in the formation or joining social movements. This is explained by the frame analysis theory (Mertala, 2017). Hence, if the person/group mobilizing and the person/group being mobilized can align in how they foresee the problems, solutions and, the perceive the organizational capacity of the mobilizer, chances of mobilization taking place is high. The alignment of the framing process between the mobilizer and the mobilized can be described as mental congruence (similarity in thought) or a convergence of rationality.

Therefore, some of the identified reasons as to why mobilization could occur include, the existence of common problems (social factor), the identification of perceived individual value (perceived value)- (value factor), mental congruence (frame related factor), and the existence and potential of the needed resources (resource related factor). However, the identified social factor is a form of frame related factor. This is because the identification of common problems is a form of diagnostic framing (Benford & Snow, 2000). Hence, the emerging factors would be the frame related factors, the value factor and the resource related factor. These factors can also be viewed as incentives, both intrinsic and extrinsic incentives, which could warrant mobilization and the willingness to be mobilized. These intrinsic factors include mental congruence, perceived value and common problems. The extrinsic factors the existence or potential of resources.

Actor Network Theory and Reasons for Mobilization

Actor Network Theory (ANT) also holds clues to the process of mobilization and being mobilized. These clues are more evident in the theorization of the theory by Michael Callon. This theorization process

by Michael Callon hold the key as to why mobilization occurs. In the ANT, mobilization occurs in two ways. The first is via the process of translation and the second is at the end of the translation process.

He theorized ANT via his observation of a group of scientist in their process of mobilizing human and non-human actors. The aim of the mobilization process was to unite the actors towards collaborating to promote a sustained production of scallops in the St. Breuic bay (Callon, 1986). The actors were the researchers, the fishermen, the scallops and scientific colleagues of the researchers that knew nothing about scallops. The researchers were the focal actors or the mobilizers. The other actors are the mobilized. In the problematization stage, the focal actors had to identify the potential resources including potential actors with which they perceive that they share common problems and perceive that, based on their plan target partners will be willing to work together with them due to mutual interest. The willingness to work together can be identified as Cooperativeness. Cooperativeness is a personality trait (see (Carriere, et al., 2019) (Gambetti & Giusberti, 2019)). The judgement with respect to cooperativeness could be either perception or evidence based. At this stage in the ANT, it is a perception. Hence “common problem” and “Perceived cooperativeness” since they indicate framing processes hence they are forms of mental congruence. However, still in the problematization stage, the focal actors (the mobilizers) had to map out a process by what each actor will do and how all the actors will work together to achieve the expected goals. The process of interposition or interressement follows this stage, as Michael Callon calls it. At this stage, the mobilizer negotiates with the identified actors towards accepting the roles assigned to them. If there is evidence of potential resources, mental congruence; individually perceived value for the mobilized; and the possibility to work together with other potential actors (cooperativeness), they will accept the invitation. Otherwise, the translation process fails. Cooperativeness at this stage is not a perception, but an evidenced based assessment. The evidence here indicates the fact that the partners are actually signing up or willing to sign up to the network. Hence, the actors are aware that the other actors are willing to work together with them. Once the actors, that are to be mobilized, accept the role assigned to them then they are said to have been enrolled. At this stage, it could be said in the literal sense that mobilization occurs at this stage. However, from the theoretical point of view, mobilization occurs at the last stage. At this stage, the mobilization of allies, is when the different actants begin to align, based on their interest and they elect one of the actants as their spokesperson in the network.

Hence, by induction, based on the four stages of translation, mobilization is possible because of the existence of potential resources, including actants, perceived value, cooperativeness and mental congruence. These factors are also intrinsic and extrinsic incentives, which are similar to those identified from the Social movement theories.

Linking the Three Theories

Based on the induction process extracted from the three theoretical approaches, a link can be identified. The link is represented in Table 1.

As seen in the table 1, what triggers motivation are incentives. These are incentives for the mobilized and the mobilizer. These incentives could be extrinsic or intrinsic in nature. The incentives identified from the ANT and the theory of social mobilization include “potential resources”, “perceived value”, “mental congruence” and “cooperativeness”. Aside, “cooperativeness”, these concepts induced from the ANT and the Social movement theories are similar.

But are these factors enough to trigger a decision to mobilize or be mobilized? In section 3 an existing model (CBNM models) that also explains why people mobilize is described. The model and the theoretical outcomes in section 2 are compared and analysed in section 4.

Table 1. The link between the three theories

Logic of collective action	Nature of the incentives	Social Movement Theories		Actor Network Theory	Main keywords
Incentive	Extrinsic incentives	Resource induced factors	Existing and potential resources	Potential resources	Potential resources
	Intrinsic incentives	Value induced factors	Perceived value	Perceived value	Perceived Value
		Frame induced factors	Mental congruence	Mental congruence	Mental congruence
				Cooperativeness	Cooperativeness

BACKGROUND 2 - ABOUT THE CBMM MODELS

The Community Based Network Mobilization (CBNM) models is a community informatics model. It emerged as one of the surprised findings in the PhD research on community mobilization. The research was aimed at finding out a suitable Public Private Interplay model for developing telecommunications networks in rural areas (see (Williams, Analysis of Public Private Interplay Frameworks in the Development of Rural Telecommunications Infrastructure: A Multiple-Case Study, 2015)). Furthermore, one of the activities in the PhD research was to identify why and how rural communities around the world develop broadband networks. Hence, the search for possibilities of implementing broadband infrastructure was the focus. A study was made of the following cases, namely the Johannesburg Wireless User Group (South Africa), Ghana Wireless network (Ghana), Dharamsala Wireless network (India), Magnolia Road Internet Coop (USA), Hallaryd Broadband Coop (Sweden), Djurslandsnet (Denmark). Data gathered from interviews, and documents from these cases were analyzed using the Grounded Theory methodology. The result of this process in that research was the emergence of the CBNM models. These models, surprisingly, highlighted the factors that led members of these communities to mobilize themselves to develop the broadband internet network.

These models had no name initially. However, as the author pondered over it for a while, it was clear that the models did provide initial insights into why community mobilization actually takes place. Hence, this model was then used to explain how people in rural areas could be mobilized to develop, 5G networks in rural areas (Williams, 2016), broadband networks (Williams, Falch, & Tadayoni, 2017), broadband networks in order to access e-government services (Williams, 2017) and later 5G Wi-Fi networks (Williams, 2018). It was in this process that the models the name of the model evolved to CBNM models.

There are four almost identical CBNM models. However, three of them are of relevance to this chapter. The three models were the developing country models, the developed country models and the universal model. The developing country models were developed from the developing country cases. These were the Indian, Ghana and South African cases. The developed country models were developed from the developed country cases. These were the Danish, Swedish and the US cases. Both models had similar constructs, but had a slight variance. Although the variance was not identified in the developing country cases, its implied implication was clear. Hence, in merging both models, the universal model was created.

In each of the models, two classes of stakeholders can be identified. These are the visionaries (the mobilizer) and the target partners (the mobilized). The visionaries and target partners are either individuals or a group. Target stakeholders could either be innovators, early adopters, late adopters or laggards as explained in the Diffusion of Innovation Theory (Everett, 2003).

Developing Country Model

The developing country model indicates that people in rural areas will decide to mobilize in order to develop rural broadband infrastructure if they find the technology useful (usefulness of technology); find the expected service useful (Usefulness of service); identify with the need the service solves (accepted user need) and have the contextual requisite resources (vital resources) to develop the infrastructure. This is represented in the Figure 1.

Figure 1. CBNM model for Developing Countries

Source (Williams, 2015)

The decision to mobilize process in figure 1 involves the “intention to deploy” and the “trial/mini-implementation”. The intention to deploy is a decision first made by the visionaries. They produce a proof of concept via the trial/mini-implementation process. A successful proof-of-concept (trial/mini-implementation) reveals the four independent constructs to the target partners. Hence, a successful trial/mini-implementation reveals the feasibility of developing the initiative as a group. This triggers the “decision to deploy” in the minds of the target partners. This results in the target partners providing their consent to join or to be mobilized to facilitate the development initiative. This iteration continues until the visionaries acquire the required critical mass needed to implement the development project.

Developed Country Model

In the developed country cases, the rural residents were already aware of the usefulness of the service and were already using the service. They were not happy with the technology used in delivering the service. Therefore, the concepts “usefulness of the service” and “accepted user need” did not emerge as precursors to their decision to facilitate the development project. However since they had access to other albeit poor services, the “intention to deploy” was a mental decision made after they were sure that a particular technology lived up to its billing in the provision of expected data rates and quality of service needed. What was also important to them was the fact that there were deployment possibilities for this technology which should be within their resources.

Figure 2. CBNM Models for Developed Countries

Source (Williams, 2015) (Williams, 2016)

Therefore, the developing country model indicates that people in rural areas will mobilize themselves to develop rural broadband infrastructure if they find the technology useful (usefulness of technology); identify deployment possibilities (deployment possibilities) and have the contextual requisite resources (vital resources) to develop the infrastructure. This is represented in Figure 2.

In the Danish and the US case, similar iterations and interaction between the visionaries and the target partners, as seen in the developing country model, was evident. This was not the case for the Swedish case. However, the reason and mode of iteration was different from that of the developing countries. In this case the mini-implementation was not a proof-of-concept. It was an actual infrastructure deployment by the visionaries, who initially had other plans towards the scaling of these networks. Hence, it was a self-mobilized effort. When neighbors saw the output of the initial deployments, they decided to sign up with the visionaries' in order to extend connectivity to their homes. It is in this manner that the visionaries were able to co-opt the target partners into the network.

The Universal CBNM model

The general CBNM model indicates that people in rural areas will decide to mobilize themselves to develop rural broadband infrastructure if they find the technology useful (usefulness of technology); find the service useful (Usefulness of service); identify with the need the service solves (accepted user need); have the contextual requisite resources (vital resources) and identify deployment possibilities (deployment possibilities). This model is represented in Figure 3.

Figure 3. Universal CBNM model

Source (Williams, 2015)

The model has 4 stages, the trigger (the 5 constructs), the decision process (intention to deploy and trial/mini-implementation), mobilization and action (implementation). The general model can be re-represented as seen in Figure 4.

Figure 4. Modified CBNM model

Based on the modification of the model the decision process, even though it ultimately leads to implementation, actually moderates the likelihood for mobilization. The model though single explains two mobilization processes. The first is the self-mobilization by the visionaries be they an individual or group. The second in the factors, the visionaries present to the target partners as a selling point in order to mobilize them. The universal CBNM models also reveal the rationality pathway for the visionaries and target partners. The decision to either mobilize /be mobilized or otherwise is a product of conviction based on rationality. The rationality pathway is guided by the existence of extrinsic and intrinsic factors. The extrinsic factors is the vital resources, while the other factors are intrinsic factors. These factors are also incentives, which actually trigger the decision to mobilize and to be mobilized. However, do these universal CBNM factors align, relate or compliment the incentives identified in section 2. If there is some alignment, relationship or complementarity, then a theory that explains the decision to mobilize and be mobilized can be expressed.

FOCUS OF ARTICLE - FROM CBNM MODELS TO MOBILIZATION DECISION.

Decontextualizing the Universal CBNM Model

As the focus of this chapter is on the decision to mobilize, hence the implementation bit of the universal CBNM model becomes irrelevant. This is because mobilization could be for any reason. Hence, the universal CBNM model of Figure 5, would then be as represented in the figure 5.

The next step is to simplify the decision process to a “yes” or “no”. The reason being that the iterations in the universal CBNM model highlighted the sufficiency of the five factors towards yield to a yes answer towards mobilization in the context of study.

The next step is to find out if the concepts identified in the theory and the independent variables of the universal CBNM model match. Since the five factors of the universal CBNM models are contextualized to the cases studied, they have to be decontextualized. To do this, the identified concepts from section 2 serve as a guidepost.

Figure 5. Conversion from CBNM model to Mobilization-Decision process

Table 2. Comparison between CBNM Independent constructs and theoretical constructs

Logic of collective action	Nature of the incentives	Social Movement theories		Actor Network Theory	Main keywords	CBNM constructs
Incentive	Extrinsic incentives	Resource induced factors	Existing and potential resources	Potential resources	Potential resources	Vital resources
	Intrinsic incentives	Value induced factors	Perceived value	Perceived value	Perceived Value	Usefulness of technology
						usefulness of service
		Frame induced factors	Mental congruence	Mental congruence	Mental congruence	Deployment possibility
						Accepted user need
				Cooperativeness	Cooperativeness	

As seen in the Table 2, there is a correlation between vital resources (CBNM) and potential resources (Keywords). However, both concepts denote the evidence or perceived evidence of the needed resources for both the visionary and the target partners. Hence, this construct can be renamed “evidence of resource”. The commonality of problems correlate with the “accepted user need”. This implies that the visionary and the target stakeholders identify the problem and that they realize and accept that they have a need. However, this factor is an aspect of mental congruence. Furthermore, there is an alignment between mental congruence and deployment possibility. This is because whatever plans are drawn as deployment possibility has to be mentally validated by the visionaries and the target partners as feasible. Hence, there has to be mental congruence before the visionary can mobilize and the target partner can agree to be mobilized. Hence, “mental congruence” is sustained as a factor. In the same vain, “usefulness of technology” and the “usefulness of service” are forms of “perceived value” first identified by the visionaries and later by the target partners. Obviously perceived value is not limited to these three constructs, perceive value could be economic, cultural, social etc. Hence, “perceived value” is chosen as a factor.

The theoretical keywords without CBNM equivalents are “common problems” and “cooperativeness”. Therefore it could be said, that the constructs in the universal CBNM models do align with some of the theoretical concepts or keywords. This would imply that the universal CBNM models on their own does explain the decision to mobilize and to be mobilized from a contextual point of view. However, it also indicates that the concepts identified in section 2 could serve as a starting point towards theorizing why the decision to mobilize occurs.

Despite this observation, how the concept “cooperativeness” does fits into the new and emerging theory. In the CBNM models, cooperativeness were not evident as a construct. However, cooperativeness was evident in the cases studied. The reason it was not captured in the data that produced the CBNM models was because the focus was not on mobilization but on implementation. However, the individuals with their selfish-ambitions would not have been mobilized if they were either mistrustful of each other or were unsure if other individuals would be cooperate. Hence, the evidence of “cooperativeness” is relevant.

Therefore, in the generalization and comparison of the CBNM models with existing theoretical outlook, it can be deduced that the incentives for mobilization are “Evidence of resource”, “perceived value”, “mental congruence” between the mobilizer and the mobilized and “cooperativeness”. If these four conditions exist, the decision to mobilize and be mobilized will occur.

Theorizing the Decision to Mobilize

Therefore, it can be theorized that the decision process towards mobilizing a person or group of persons to perform a certain action will occur if the following conditions are satisfied. These are the evidence of needed resources, the mental congruence between the mobilizer and the mobilized; the evidence of either actual or potential cooperativeness and the perception of individual value to be derived from the action to be performed.

This theory is called the Mobilization-decision theory. The decision process is positive if the person or persons to be mobilized are actually mobilized. Hence, the perceptions of the visionary was correct. If the result is otherwise, then there was a misjudgment of the perceptions by the visionary. The diagrammatic representation of the theory is shown in the diagram below.

Figure 6. Mobilization-Decision Theory

The decision process is the factor and as mention earlier, it is either a “yes” or “no” decision. The determination of the different relevant variables, bases on social theories can be determined statistically. Furthermore, the weight determinant of the four independent variables which would indicate if the decision will be “yes” or “no” can be determined statistically.

However, if one intends to mobilize others then the four factors, supported by the explanation of each factors, in this paper can serve as a “shopping list”. This shopping list would act as a selling point to the person or group to be mobilized. If the mobilizer is satisfied with the “shopping list”, then the decision to self-mobilize is “yes”. At this point mental congruence will be an assumption. It can only be verified once the target partner grants a confirmation. In the same vain, if the mobilized is satisfied with the target partner is satisfied with the “shopping list”, and then the decision to be mobilized is “yes”. Otherwise the decision will be “No”.

Hence the mobilization-decision theory can be contextualized for the visionaries (the mobilizer) for self-mobilization and the target partner (the mobilized).

For the visionaries, it can be theorized that the decision process towards mobilizing themselves and other persons or group of persons to perform a certain action will occur if there is:

1. An evidence of needed resources;
2. Perceived mental congruence with the target partner;
3. the evidence of either actual or potential cooperativeness with and between target partners;
4. *and the perception of individual value to be derived by the visionaries and the target partners from the action to be performed.*

For the target partners, it can be theorized that the decision process towards a person or group of persons allowing himself or themselves to be mobilized to perform a certain action will occur if there is:

1. An evidence of needed resources
2. A mental congruence with the mobilizer;
3. the perception of either actual or potential cooperativeness with the mobilizer and other target partners;
4. *and the perception of individual value to be derived from the action to be performed.*

Mobilization-decision theory works for individual to group mobilization efforts and group-to-group mobilization effort.

SOLUTION AND RECOMMENDATION - THEORETICAL AND PRACTICAL IMPLICATIONS MOBILIZATION-DECISION THEORY

In principle, the mobilization-decision theory can be used to explain why people mobilize themselves and why they mobilize others. It can also be used as a framework for mobilizing people. In order to do so, theories such as Resource mobilization theory could aid in the identification and acquisition of resources. Frame analysis theories could be used as an aid to identify the approach towards identifying the worldviews required. The mental congruence could be either prognostic, diagnostic or motivational (Benford & Snow, 2000). Economic theories explaining value and value added theories of social movement can be used as an aid to identify the relevant value factors needed. Moreover, the theory of cooperation (Gardner, Griffin, & West, 2016) can be used to identify relevant factors that could serve as a frame and evidence that could serve as a basis for harnessing or identifying cooperativeness among potential target partners.

Aside its explanatory powers, the mobilization-decision theory, which borrows a great deal from the social movement theories also complements these theories. This is because the mobilization-decision theory is more explicit on the possible reasons individuals and groups decide to mobilize or be mobilized into social movements. Furthermore, the theory adds an insight in which academics could build upon or modify in order to understand why mobilization occurs and the power relations involved in the mobilization process.

Aside the theoretical implications, there are practical implications as well. The practical implication is not just in the academia but also in different types of organization. The bigger the organization, the bigger the need to create small manageable teams or task forces. In each of these teams, the visionary is often the leader of the team and this leader has to mobilize the team members to perform different tasks. Although team leaders are more likely to coerce, research indicates that coercion could result in resistance and unhealthy working environments (Truter, 2008) (Armas, De Leon, Santos, & Vitug, 2019). Hence, team leaders have to adopt innovative ways and means of getting their team members to see the need to work on a project. They have to be mobilized and be willing to be mobilized. Furthermore, in organizations, a member of a team could have an idea. At that moment, the team member is the visionary. That team member using the motivation-decision theory as a guide may successfully convince the mid-level or high-level management to embark upon the vision. Hence, the mobilization decision theory serves as a good tool.

Furthermore, still on the practical implications within the dimensions of culture, politics, education and the economy to mention a few. In each of these dimensions, there are ideas that warrant collective action. As examples, in the case of culture, the idea could be the desire to either promote or preserve cultural heritage. In the case of politics, the idea could be the case of promoting a political ideology. In the case of education, the idea could be the desire to produce more female engineers within a society. In the case of the economy, the idea could be the desire to transition from a command economic system to a market based economic system. The ideas identified in each of these examples, will only remain as ideas until a person or group of persons (visionaries) decided to act upon the ideas. These ideas require collective action. However before collective action, based on free will, can become possible then the visionary must be able to identify the perceived value of the idea, the evidence of resources for the idea, evidence of potential collectiveness among the target partners and evidence of mental congruence about the problem to be solved and the proposed solution. If the visionary is convinced by the weight of evidence emerging from these four factors, then the decision to mobilize the target partners will be made. At this point, the visionaries are mobilized to the idea. If the visionaries are able to convince the target partners of the existence of these 'evidences', then the target partners will buy into the idea, and allow themselves to be mobilized. This analogy is evident in the formation of political parties, development of government policies, think tanks, government committees in a democratic system of government, in the adoption of educational systems etc.

Apart from organizations and other practical cases mentioned, mobilization is also critical in society, not just for social movements, but also for community mobilization initiatives, such as those that produced the CBNM models. There are various areas in the world where government resources are insufficient to deliver the requisite social amenities or social programmes. If community leaders, guided by the principles of this theory could be able to facilitate cooperativeness, identify a way of getting resources, embark on a change management process to instill value and a worldview of the solution among the community members. If they succeed in this process, they could easily mobilize the community to facilitate the much-needed social amenity or social programme.

FUTURE RESEARCH DIRECTIONS

Mobilization is an ongoing activity, which will last as long as there are living organisms on earth. At every second in life, there are persons who are at the point of making a decision towards mobilization. On the other hand, there are persons who are either mobilizing, or are at a point where they are pondering on whether they should accept being mobilized or otherwise. Hence, there exist a great deal of possibilities for the application, testing, the evaluation and upgrade of the Mobilization-decision theory. The possibilities are research possibilities, which could be approached either quantitatively, qualitatively or via the mixed method approach, irrespective of the governing research paradigm and research approach. Based on this premise, future research directions can examine how the decision to either mobilize or be mobilized can be triggered or was triggered in the following context among others. These contexts could either be sociological, economic, historical, Psychologic and other aspect of the social sciences.

Another aspect for research using this theory would be to understand, if the same principles work for collective action performed by non-humans, such as machines. Obviously, the trigger here would be humans. If the theory holds, or serve as a foundation for understanding how to enable machines and other non-humans, then its applicability will be useful for engineers. Which would imply that engineers could use the theory as checklist for understanding if a machine will operate or not. This idea is far-fetched now, but it is a research opportunity.

In relation to this book, the future research direction will be to use the theory to explain the decision to mobilize in organizations. This decision could be at the lower management, mid management and upper management level of organizations. The explanatory power from the theory has the potential to expose the strength and weaknesses in the mobilization effort of either an organization or a unit. The mobilization effort could be geared towards knowledge management efforts, mobilization of capital and the mobilization of labor etc.

These are some areas for future research.

CONCLUSION

The aim of this chapter was to theories the decision to mobilize from observations made in social theories and the CBNM models. Mobilization-decision theory is a social theory; it is a mid-ranged and generalizable to a certain degree. It is a theory with a greater latitude of applicability in various aspects of life, where mobilization of people occur. It highlights the factors that will result in a decision to embark on a mobilization process. It also highlights factors that highlight conditions by which human agents will be agreeable to being mobilized for whatever agenda as free agents. Hence, it provides an initial theoretical explanation on why the decision to mobilize and be mobilized occurs. Obviously, it is foundational theory, more work is needed in the form of validation. Furthermore, it is open to modifications as evidence emerge on why people decide to mobilize.

KEY TERMS AND DEFINITIONS

Collective Action: A collaborative or cooperative action performed by a group of people, governed by self-interest, aimed at achieving a common vision.

Community Mobilization: The process where a group of humans participates in a collective decision-making aimed at influencing situations that affects the group.

Mobilization: The process of assembling and engagement of resources in order to perform an action.

Mobilization-Decision: This can imply either the decision to mobilize or the decision to allow oneself to become mobilized to perform an action.

Mobilization-Decision Theory: This is a theory that explains why mobilization occurs and why people decide to allow themselves to be mobilized.

Moral, Social, and Political Responsibility in the Information Age

11

Tomas Cahlik

Charles University, Prague, Czech Republic

INTRODUCTION

Information and Communication Technologies (ICTs) have penetrated during the last 20 years all human activities everywhere on the Earth. Humanity has entered into the information age, virtual reality and even virtual worlds have been created, serious discussions are led about possible impacts of Superintelligence that could be created in not so distant future.

Basic questions of moral philosophy stay as they have always been: How are we to live? What are we to be? Basic answers are, of course, that we ought to live good lives and be good persons. Humans are social beings, that is why moral, social and political philosophy overlap. Basic questions of social and political philosophy have been always concerned with informal and formal rules in social and political structures, companies and states being the most relevant for this article. Basic answer is that rules ought to be equilibrated in the sense that social structures function well and are just. Equilibrium is not petrified; it must reflect current conditions of social and political life.

What does responsibility mean? Everybody is morally responsible: she must be able to respond to questions about her life and personality; to explain what she does and why. Leaders in all social and political structures (families, schools, churches, companies, states ..) are socially and politically responsible: they are responsible both for functioning of their structures and for the latter being just.

What are just structures? This is a complicated question with many possible answers. For the purpose of this article, we stress just three important attributes of justice: people are not exploited, are not alienated and are as free as possible.

The aim of this article is:

- To specify what “living a good life” and “being a good person” could be in the information age;
- To identify some challenges and opportunities ICTs offer for good rules in social and political structures.

Having absolutely stabilized basic questions and basic answers makes the methodology of moral, social and political philosophy quite different from the methodology in sciences. In sciences, one starts with a thorough review of previous research, specifies some new and interesting research question, makes hypotheses about possible answers and bases argumentation on data. In moral, social and political philosophy, one reflects problems of the current age in mirrors that were created centuries ago and have been polished by many reflections ever since. Forms of texts are rich: dialogs, even poems, but the most used form is an essay.

DOI: 10.4018/978-1-7998-3479-3.ch099

BACKGROUND

Literature review in research articles is used for showing that the research described in the article fits into research themes that are interesting for contemporary research community. Literature review in ethical reflections is used differently, just for illustration of ideas that have been published in the area of interest and for “opening the scene”.

Looking into the Web of Science Core Collection database in May 2019 and using keywords “information technology” and (“moral responsibility” OR “social responsibility” OR “political responsibility”), in the whole timespan from 1945 to 2019 there are 108 entries obtained (from that 107 articles or conference proceedings). 20 entries were published from 1992 to 2009, 33 entries from 2010 to 2014 and 55 since 2015. This reveals not high but steady and increasing activity on the interdisciplinary border between ICTs and moral, social or political responsibility.

Looking closer into the content of those articles, following themes can be identified since the year 2010:

- Ethical questions linked with the creation and use of “big data”, including creation of agreed standards of good practice - e.g. (Rizk&Choueiri, 2006), (Light,& McGrath, 2010), (Celen, & Seferoglu, 2013), (Chen, B., & Zhang, N., 2016);
- Development of sustainable information society - e.g. (Tsai&Chen, 2013), (Busch, 2011), (Nieme la&Ikonen&Leikas&Kantola&Kulju&Tammela&Ylikauppila, 2014) in the sense of an inclusive and environmentally friendly society; application of precautionary principle in the development of ICTs (Som&Hilty& Kohler, 2009);
- Corporate social responsibility of both ICT suppliers and users – e.g. (Arevalo-Ascanio, J. G., Bayona-Trillos, R. A., & Rico-Bautista, D. W., 2015) (Tsai&Chen, 2013), (Busch, 2011), (Vaccaro&Madsen, 2009), (Chuang, S. P., & Huang, S. J., 2018), including suggestions for standards of good practice (Patrignani&Whitehouse, 2014), (Zompras, A., & Siakas, K., 2015). and how to enable consumers to push companies to behave ethically with the use of ICTs (Watts& Wyner, 2011), (Choi, S. B., Feng, Y. T., Liu, J. J., & Zhu, Q. H., 2019);
- University social responsibility (Arntzen, 2010); new teaching and learning culture based on ICTs (Stepien, 2010), (Kozhamkulova, Z. Z., Amankeldikyzy, N., & Kabaeva, D. A., 2017), (Chen, Y. F., 2016);
- Social responsibility in different ICT supported activities – e.g. bicycles’ sharing (Zhao, X. X., 2017); police service (Ramos, S., Perez-Lopez, J. A., Abreu, R., & Ieee., 2017), media (Lee, C. G., Sung, J., Kim, J. K., Jung, I. S., & Kim, K. J., 2016).

This indicates research activity that is driven by applications and can be contrasted with the research activity from the years before, that was pushed by theoretical considerations. (Lianos, 2000) e.g. starts with sociological concepts and identifies the threat that ICTs can atomize society through making development of personal trust obsolete. Lianos uses credit card as an example: one does not need to be trusted by the provider of money, the only thing that is relevant is the validity of the card. Technical norms replace moral and social norms.

Research fields may have different dynamics. It is quite usual that after the theoretical development some themes or even the whole field dissolve in applications. Nevertheless, after some time, both practitioners and applied researchers may find it useful to return to more generalizing theoretical reflection. In this article, the most general level of ethical reflection is being considered.

Moral, social and political philosophy offer a lot of valuable ideas that have been generalized from the real life problems of the whole human history. In this article, especially ideas developed by utilitarian philosophers, existential philosophers and the proponents of the “virtue ethics” can be identified. Two more areas of ethics linked with this article are “ethics of norms” and “casuistry”. Two ideologies are shortly compared in this article: Liberalism and Marxism. Readers are advised to find more detailed summaries of those three schools, two areas and two ideologies on web.

“LIVING GOOD LIFE”, “BEING A GOOD PERSON” AND “HAVING GOOD RULES” IN THE INFORMATION AGE

Issues, Controversies, Problems

Let us identify three challenges and three opportunities ICTs directly offer in the context of this article. This gives us a framework from which the discussion of economic costs and benefits stays mostly out, even if economic costs and benefits surely have moral, social and political impacts.

Specification of the **first challenge** builds upon the above described conclusion in (Lianos, 2000) that technical norms replace moral and social norms. Problem is that the network of moral and social norms has always been considered as something absolutely necessary for the identity of specific society and that the dissolution of this network means atomization and threatens the whole society.

The second challenge is linked with the current research frontier of ICTs, with virtual reality. Economic and social thinking is strongly based on utilitarianism and its basic persuasion that for having a good life pleasures must be maximized and pains minimized. ICTs allow creating a virtual reality in which the choice of pleasures is almost unlimited and in which we are able to avoid pain. The basic question here is the authenticity of such a life. It can be easy and pleasant but it loses any sense.

Above the basic utilitarian life level, another level ought to be built in which we ask if our activities are right. What is the right activity has been discussed in Western thinking for centuries since Plato and two basic outcomes are as follows:

- In a right activity, humans are used not as tools only. E.g. authors of new software ought to take into consideration not only how much they earn but if the software allows better self-realization of users, too;
- Real circumstances must be taken into consideration in following the basic target of “being better humans”. E.g. software firms must follow the profit motive as well as the moral one to stay in the business.

ICTs have not changed these basic outcomes but have surely changed the real circumstances and this opens the stage for discussion of what the right activities are in these changed circumstances. All new technologies have always done this, but what makes ICTs specific is the scale and speed of change.

One lives a good life if one realizes his or her potential in right activities. A person can develop its potential and become a virtuous person through cultivating its virtues and fighting its vices. Good people are virtuous people and there exists a positive correlation between being good people and doing right activities. So there exists a strong link between being a good person and living a good life.

The **second challenge** of ICTs lies in the possibility that people could be sucked too much into the virtual reality, enjoy pleasures there and try to avoid reality. Their lives would lose authenticity and

they would not leave the basic utilitarian life level. Impacts on both the individual and society would be analogic to impacts of drugs addiction.

There exists a positive feedback between the first and second challenge: instead of being identified with a real society existing at some geographical place, people are identified with the usually anonymous social group sharing the same virtual reality. In the process of atomization of real society, the motivation for its members to find substitutes of social ties in virtual reality increases. This closes the loop.

In this context, we could ask about the geo-political impact of having socially atomized countries in which a lot of citizens avoid reality together with socially homogenous countries where people live more in reality. Let us imagine a possibly violent conflict and ask who would probably win in such a conflict? Or let us imagine mass immigration of people from the second type of countries to a country of the first type. What would happen? It is surely not socially responsible to ignore these scenarios.

The **first opportunity** of the virtual reality ICTs have created lies in quick detection of suspect economic, political and other social activities in a real society and in facilitating the discourse about such activities. By definition, discourse is discussion in which participants are free in the sense that they are not influenced by exogenous incentives or constraints in the expression of their opinions. Virtual reality, if it is free - without censorship - and anonymous offers an optimal environment for discourses on any topic. Discourses on suspect social activities help to create socially accepted moral norms and push firms and politicians to social responsibility.

The **second opportunity** lies in the enormous educational potential of the virtual world. For Aristotle, being educated was considered to be a virtue by itself, even if not being a moral virtue. For Plato, if people just knew what were right they would behave in that way. It may be too optimistic but we know that there exists a negative correlation between educational level in a country and e.g. crime.

Instead of discussing this intuitively clear opportunity on general level let us illustrate how ICTs can be used for benchmarking and looking for best practices in ethical issues. In (Codes of Ethics Collection), there are thousands of different ethical codes. Each of them presents norms that have been accepted by some organization (firm, association, university etc.). Ethical Codes are classified according to professional categories, one of them being "Computer and Information Science". In May 2019, 116 organizations are found in this category (in September 2015, just 56), some of them with ethical codes for specific activities, some of them with different versions of the same code showing how it has been developed in time.

Any organization interested in development of its ethical norms can use this enormous source to compare the norms it already has with norms of its peers in the Codes of Ethics Collection. In an internal discourse, it can then formulate and accept the best for itself.

We can see another positive feedback, now between both opportunities: educational material easily accessible through ICTs can be used in discourses and additional knowledge created in discourses becomes easily accessible through ICTs.

The **third opportunity** lies in using ICTs for supporting the creation of virtues and the **third challenge** in suppressing the creation of vices. The lists of moral virtues and vices have been changing during the centuries since Aristotle and there is not full consent about what ought to be on the lists. The most of virtues and vices get stronger with the repetition of either good or bad activities.

Let us take the (List of virtues) and (List of vices) from the webpage <https://www.virtuescience.com/>, choose some of them and analyze how they can be strengthened by ICTs. (We could surely take any other list, but the advantage of these two lists is that the list of virtues has much more items than the list of vices. This supports the optimistic attitude towards human nature.)

“Compassion” and “Charity”: ICTs allow watching repeatedly and with high frequency poor people around the World what develops compassion among the most of watchers; psychologically especially among young people who are in the same time the most knowledgeable users of ICTs. This positive correlation can make this effect quite strong. ICTs offer a very easy way (e.g. donation through SMS) to do charitable activities what makes compassionated people to do such activities repeatedly. This strengthens the virtue charity.

“Curiosity”, “Commitment” and “Creativity”: Anderson in (Anderson, 2010) describes a nice example how web video powers global innovation. A slum boy watches video with street dance. Watching wakes up his curiosity and he makes commitment to master street dance himself. He surely has to be highly creative in transferring the knowledge from video into reality. There are millions of different activities and millions of web users, many of them behaving similarly as the slum boy, so ICTs have a very strong effect on these three virtues.

“Chastity” as a virtue or “Lack of Chastity” as a vice: In this context, pornographic content of web sites ought to be discussed. Watching pornography repeatedly creates habit - sometimes addiction – and weakens chastity. This discussion is not relevant for all World societies, e.g. in Japan people do not consider chastity as having sexual context. Watching pornography is clearly linked with the second challenge of ICTs discussed above; real sexual activity can shift to virtual reality what could have demographic impacts.

“Sloth”: Let us understand laziness as aversion to be active in the real world. Being active in that part of virtual reality that overlaps with reality perhaps weakens sloth; ICTs can increase the efficiency of our real activity what increases our motivation for doing it. Problem is that ICTs have created an enormous potential for procrastination – for doing less urgent but pleasurable tasks in preference to more urgent but less pleasurable ones. The seductive power can be strong and yielding to temptation is surely positively correlated with sloth.

“Enthusiasm” and “Cooperation”: For economists, it is really difficult to explain the very existence of the open source software or Wikipedia because of non-existence of material incentives. Possible explanation is following: Knowledgeable users of ICTs are usually quite enthusiastic about the possibilities ICTs offer. They form a global community and identify strongly with this community. This has created the situation in which they like to cooperate not for material benefit but for achieving a shared goal. This works if individual costs of cooperation are negligible, what they with the use of ICTs can really be. Social benefits are enormous.

“Cooperation” is linked with the problem of coordination. There has always existed a trade-off between order in social structures and personal liberty. Social structures have their functions and coordinate individuals according to their functions. They put constraints on the behavior of individuals; the latter pay a “liberty tax” and get material, social and political security in exchange.

One of basic structures are companies. Since the 19th century, there exists a controversy between Marxists and liberals about justice of capitalist companies. Marxists stress the exploitation of workers by capitalists and the alienation of labor; workers are just tools for the creation of profit, wages are costs as any other costs and workers are cut-off from the results of their work. Marxist solution is socialist revolution, dictatorship of proletariat, nationalization of private property and bureaucratic coordination. Liberals stress the loss of liberty linked with Marxist solution and worse functioning of socialist economies compared with capitalist economies.

ICTs have potential to make this conflict less severe. The existence of platforms supports self-employment, where problems of exploitation and alienation do not exist. Airbnb has created millions of self-employed hoteliers, Uber millions of self-employed taxi drivers. Networks of self-employed

professionals linked with cell phones can deliver complex reconstruction services in housing in such a quality as traditionally organized construction firms. And there are many other examples.

All this works because ICTs have brought a new dimension into the creation of trust, the basic condition for successful cooperation. Before: trust was based either on personal links in small local communities or on the authority of state and big companies. Today: giving “likes” or other form of evaluation to services offered on web has this trust-creating effect.

It is understandable that traditional companies do not like this; it is a new type of competition for them. They use very often their lobbying power to try to forbid these platform based services. Responsible political reaction is surely not to forbid these services, but to find ways how to harmonize the new opportunities with the traditional thinking.

Very interesting question is linked with crypto-currencies. Their existence undermines the monopoly of the state to issue fiat money. Acceptance of fiat money is based on trust enforced by the state. Blockchain as the basic technology crypto-currencies are based on has a trust-creating potential that can replace the trust guaranteed by the state. Again, responsible political reaction is to find ways how to harmonize traditional forms of currency with crypto-currencies. It can be difficult for politicians to be responsible in this area because it undermines one of the economic reasons for the existence of the state.

Solutions and Recommendations

The positive impact of above discussed opportunities can neutralize or outweigh the negative impact of above discussed challenges - threats. We cannot say for sure what happens because we know that all systems with positive feedbacks can considerably and discontinuously change very quickly their behavior and that it is impossible to predict when the change comes and what the behavior of the system would be after the change. Similar situation has occurred with the spread of each new technology and some recommendations can be done based on historical experiences.

It would not have any sense to try to stop the development of ICTs, it is simply impossible. What is possible is to try to increase the costs of ICTs activities that are negative from the ethical point of view and to increase benefits of activities that are positive from the ethical point of view. If it ought to be done, how to do it and who ought to do it opens a lot of questions. Let us take as an example the possibility of censorship.

Censorship can decrease negative impact through forbidding access to pages that could create addiction. Problem is that it constrains freedom in the virtual reality that is the basic condition for using up the opportunities of ICTs. In each society, some equilibrium level of censorship has been created that reflects different opinions on this issue. Both opinions and the equilibrium shift in time, we can imagine that in Western societies more www pages than child pornography could be blocked and in China some of the currently blocked www pages could be unblocked.

Previous example shows that discourse of ethical issues linked with ICTs can never stop and that all members of society have responsibility to take part in it.

FUTURE RESEARCH DIRECTIONS

Following research questions would deserve more attention:

- What is the impact of ICTs on social identity? Could possible changes in social identity have a geo-political impact?
- What other virtues and vices are influenced by ICTs and how?
- Is it possible to increase the costs of ICTs activities that are negative from the ethical point of view, ought it to be done and by whom?
- Is it possible to increase the benefits of ICTs activities that are positive from the ethical point of view, ought it to be done and by whom?

CONCLUSION

ICTs offer a lot of possibilities and present some challenges – threats – to everybody for living a good life in the ethical sense and being a good person. To leaders in different social structures – companies and states being the most relevant for this article, ICTs present possibilities for the development of more efficient and more just rules.

It is impossible to predict if the positive impacts outweigh the negative ones. Anyway, it is impossible to stop the development of ICTs. The question is if the society ought to try to increase the costs of ICTs activities that are negative from the ethical point of view and to increase benefits of activities that are positive from the ethical point of view, who ought to do it and how. All members of society, but especially its leaders have responsibility to participate in discourse about this question.

KEY TERMS AND DEFINITIONS

Blockchain: In informatics, a special type of a distributed decentralized database with growing number of records that are linked with the use of cryptography. It is resistant to any modifications.

Casuistry: Branch of ethics that uses case studies to make clear moral principles and norms in typical situations. All ethical codes specify some norms of conduct. These norms are usually explained with the use of different case studies.

Crypto-Currencies: Digital assets that are based on blockchain (or other advanced information technology) and can fulfill similar functions as money.

Ethics: Practical philosophy, scientific analysis of moral contents.

Ethics of Norms: Branch of ethics that analyses the structure of norms and what they are based on.

Existential Philosophy: Branch of philosophy that starts with individual existence and the problem of its being in the World. Important predecessor was Søren Kierkegaard (19th century), among main representatives we can find Martin Heidegger and Jean-Paul Sartre (both 20th century). They looked for authentic existence and have found different solutions depending especially on the religiosity of the specific philosopher.

Liberalism: It is (not only) an ideology aiming at personal liberty, rule of law and consent of the governed.

Marxism: It is (not only) an ideology aimed at equality and building of a classless society.

Norms: Norms are the shared and sanctioned rules. Sanctions can be both formal (e.g. law) and informal (e.g. pressure of social group).

Utilitarianism: Branch of ethics that bases moral reasoning on consequences of actions. Actions are good if they maximize pleasure and minimize pain. Among grounders are Jeremy Bentham and John Stuart Mill (18th-19th century). It has penetrated the mainstream economics. It can be shown that total utility of consumers can be increased by redistribution.

Virtual Reality: Created and accessed by ICTs. It usually overlaps with “reality,” but the overlapping is changing and fuzzy. Extremes of Virtual Reality are Virtual Worlds, in which “avatars” of humans can live parallel lives.

Virtue Ethics: Branch of ethics that considers humans as being bearers of given or developed virtues. Humans have to develop virtues and fight with vices for becoming good. Basic concepts go back as far as to Plato and Aristotle (5th, 4th century BCE).

The Voice of Social Media, 1997–2018

Cook Communication, USA

INTRODUCTION

Today's social media constitutes communication portals where anyone can sign up and freely "post" messages to self-selected groups of individuals. It includes three key elements: (1) a public or semipublic profile within a bounded system, (2) a list of other users with whom they share a connection, and (3) the ability to view and traverse their list of connections and those made by other users in the system¹. (Che & Ip, 2017)

Social media can be seen as ground-level communication as opposed to the alternative - mass communication. Within some ill-defined limits, individuals can post anything they want on Social Media, while communication on mass media is heavily edited by gatekeepers – those who create, develop and edit public communication. As early as 1975 Janowitz (1975) presented the gatekeeper role in journalism as a method for reporting information with scientific method for objective and valid results. In the same article, however, he compared the journalist's gatekeeper role with that of being an advocate. Surprisingly, this contrast was to reappear decades years later in communication via social media.

While most individuals haven't sought to be journalists, freedom of expression naturally accompanies the desire for individuals to publish their own ideas. Thus, when social media arrived, many individuals joined the social media movement.

Social Media as Mass Communication by Individuals

The concept of "mass communication" has traditionally represented a one-way flow from source to recipient. Early writings in communication theory also featured feedback and context, but mass communication remained a broadcast to the masses (Schramm, 1954). Before examining its properties, one might consider the state of communication late in the 20th century.

In the last decade of the century, Berger (1995, p. 7-9) distinguished between individualism and communication to large population groups. At that time, individuals could hope to communicate with persons outside their acquaintance, but it was difficult to "reach the masses". At mid-decade the new Internet had developed from small networks to the extent that it was seen as a mass medium of communication (Morris & Ogan, 1996). However, even with the Internet, the individual's ability to access the web to reach the public was limited by cost and technology.

Throughout these formative years, the main concept in mass communication was to broadcast news and entertainment into homes from a central place. News editors served as gatekeepers, automatically limiting news content. Their news stories were received in homes and, as long as the number of networks was limited, viewers, readers and listeners could discuss the shows with friends and family the next day.

When the Internet arrived, unpublished writers hoped to gain access there. In reality, it was difficult and expensive to start a website that would ever attract a large public audience like that of radio and television

DOI: 10.4018/978-1-7998-3479-3.ch100

broadcasting. And, quite naturally, those websites with many visitors simply basked in their monopoly status and continued limiting access to the Internet in the same way radio and television always had.

In retrospect, the main question must have been— who was permitted to originate news content? The average person could never hope to be “on the show”. In fact, it was clear that only the media managers, producers, and directors could decide. If they said your news wasn’t important, it wasn’t important. While many people had a desire to be “on the air” to share their ideas, this was impossible for almost everyone. Access for the average person was denied.

Background

Individuals were able to publish their own content starting in the 1980’s with the public Bulletin Board Services (BBS). The BBS was sort of a hobby medium on the early Internet service. (Kayingo & Hass, 2017) Here an individual could locate a “bulletin board” covering a specific area of interest and communicate with other individuals who had made the same choice.

The first Bulletin Board System (BBS) was created by two hobbyists in Chicago who wanted a way to inform friends about meetings, post announcements, and share interesting information. (Langmia, Tyree, O’Brien, & Sturgis, 2013).

As such, today’s social media model did not emerge until 1997 with the advent of the first social site sixdegrees.com. (Boyd & Ellison, 2007). Some web users started first “weblogs” in the same year (Oxford English Dictionary, 2015) and the word “social media” first appeared (Bercovici, 2010). Another service, ChinaRen Alumni was created in 1999, as China’s first network community that matched the social network model.

How did writers gain access? In 1999 a new trend for access emerged with a small website called Author-me.com. Its purpose, according to the Internet Archive, was as follows:

We nurture new writers who pursue a dream of publishing their work. We offer a chance to protect each manuscript, web-publish it, and receive private comments on it via your e-mail address. Here’s a bit of encouragement during the tough process of refining your writing skills and submitting manuscripts for publication.

As social platforms became established and were adopted by many users, services such as LinkedIn (started in May 2003) began to transition from a ‘web of things’ to a ‘web of people’.

It was not until the launch of MySpace (2003), Facebook (2004) and Twitter (2006) that social networks gained widespread popularity. (Schoop, 2017). Soon these same websites converted to a new concept. Free Internet participation was available to anyone, and the social media bubble burst. This radical development began with very little fanfare.

Facebook was established by Mark Zuckerberg at Harvard University. At first, the website simply offered commercial database services on about.com. At about the same time, alternative social media websites MySpace (founded by Chris DeWolfe and Tom Anderson) gave access, along with Twitter. By 2006 Jack Dorsey, Noah Glass, Evan Williams and Biz Stone were discussing the idea of using text messaging to share “statuses”, etc., which form the basis of today’s postings. (Furlong, 2013).

As social media developed, for commercial reasons, it became important to “track” the number and location of viewers of specific pages. (Xiang & Fesenmaier, 2016). Further, users could publish “profiles” showing their background and interests. (Eastin, 2010).

The Pew Research Center first started tracking social media platform adoption in 2012 (Remland, 2016). By 2018 they could summarize: “When Pew Research Center began tracking social media adoption in 2005, just 5% of American adults used at least one of these platforms. By 2011 that share had risen to half of all Americans, and today 69% of the public uses some type of social media.” Further analysis revealed that: “As more Americans have adopted social media, the social media user base has also grown more representative of the broader population. Young adults were among the earliest social media adopters and continue to use these sites at high levels, but usage by older adults has increased in recent years.” (Pew, 2018)

Multi-level Communication

Unlike journalism, the social media phenomenon permits a vast number of inputs to communication. Any user can post a profile or “status,” and any interested viewer can comment back in public or private messages. Many users can employ instantaneous reporting of a new thought, issue, or an incident, and in many cases an eyewitness account as well.

Due to the personal origin of these messages, and because any individual can post messages, social media sought a high level of credibility. The message reflects ideas of individuals, and the communication is less vulnerable to the advocacy foreseen by Janowitz in 1975 - political and economic pressures

which drive news on the broadcast media. Thus, social media can supplement main media and reflect a broader scope.

Social media also has an important role in free speech. In cases where government censorship blocks legitimate news, as has been the case in Iran, social media can provide an eyewitness account (Rahimi, 2011). This enables individuals to undermine censorship by repressive governments and helps to inhibit false propaganda. Since the reports are immediate, there's much less chance of bias in reporting. In cases when such reporting is extreme, it's possible for other witnesses to contest and correct the original posting. This is the self-correcting feature of social media.

Erik Qualman's book *Socialnomics* (2013) makes this comment:

The good news is that in this new world order, once you have determined your initial messaging strategy, you have the ability to tweak it for relevancy based on feedback....

Extreme viewpoints can be damaging to productive dialogue, but on social media it's typical for extremist views to be followed by contrary comments, leading to more useful conclusions.

The most popular postings are called "memes," and they are said to "go viral" because thousands or millions of communicators choose to "share" them with their friends and contacts.

Ideally, the development of social media led to an expectation that communication would be personal, often a conversation among acquaintances or like-minded individuals. Surely this would characterize early postings on Facebook and other social media. For these reasons, social media offers untapped potential to build harmony into international communication.

Social Media as an Instrument for World Harmony

This new medium of social media may well represent the most effective venue for building peace in today's troubled world. Occasional news stories cover evil actions in today's world, but social media can quickly assemble members into groups that mobilize and help to shift world opinion from fear to action. And, for perhaps the first time in world history, communication – not weapons – can turn the tide toward peace and harmony.

A recent "snapshot" of scholarly literature on social media and peacemaking (Cook, 2018) found considerable hope in several findings:

- 1) Social Media Supports Clustering of Citizen Groups
- 2) Social Media Influences International Relations and Activism
- 3) Social Media Communicates in Crises

In his book *Tweets and the Streets*, Paolo Gerbaudo (2012) examined the relationship between the rise of social media and the emergence of new forms of protest from the Arab Spring to the 'indignados' protests in Spain and the Occupy movement, thus illustrating the power of this medium.

From these findings it is clear that social media can quickly (albeit temporarily) mobilize support for peacebuilding efforts. While it's important for peacemakers to seek negotiated solutions, develop research reports and theories, and create artistic and educational expressions, it's important to give new attention to populist efforts to solve long-standing political rivalries and entrenched political interests.

Social Media as Activist Communicator

Social media has taken on an advocacy role which is beginning to rival that of the communication networks. While Mark Zuckerberg was a founder and developer of social media, later he had to apologize because his company shared user data with Cambridge Analytica, a company which is reputed to have used the data to affect the outcome of the US 2016 Presidential Election (Persily, 2017).

Even more surprising in the deliberate use of the social media network Twitter by Donald Trump, the President of the United States, to use daily “tweets” to communicate his personal view of political events to millions of followers (Lester, 2018), thus bypassing the gatekeeper and advocacy roles of journalists who do not share his personal views. Kellner (2018) characterizes this phenomenon as “Donald Trump and the War on the Media.” Further, similar activities by world leaders are occurring with other world leaders: Narendra Modi, Nigel Farage, and Geert Wilders (Thawani, van der Vlugt, Out, & Chandra, 2018).

Such activities have not escaped the attention of broadcast media and political parties, and social media is no longer simply seen as an alternative to dictatorial governments. However, as in experience with repressive governments, serious attention is being given to censoring content in social media. This is quite a break from the freedom of communication which first characterized social media platforms. As of 2018, Pew Research found that 72% of a sample of US adults thought social media platforms intentionally censor political viewpoints (Moon, 2018). While these controls are socially responsible, they may also constitute censorship or advocacy.

A 2018 editorial in the New York Times on suppression of “hate speech” had this comment: “If we allowed these voices to be silenced on grounds that they promote hate, we’d find ourselves scrambling to defend the radical poets, musicians, filmmakers and other artists who have pushed the boundaries of expression into what could arguably amount to hate speech, but who have done so from the vanguard of social and political protest.” (Nielsen, 2018).

Regardless, Facebook deleted posts by individuals and groups which seek to publish highly questionable, inaccurate, or inflammatory content. (Ng, 2018), (Keller, 2018). While this may seem a temporary reaction to criticism, social responsibility in content is becoming a necessity (see Weaver, 2018).

Further Research Directions

The Internet and social media radically broadened the scope of mass communication research beyond radio, television, and newspapers. While it has been common to lament errors and bias in news coverage, the introduction of social media transformed the picture by offering free speech in public to everyone. While this would seem to satisfy the critics, recent problems with social media have made it the new monster in the room. Now social media platforms stand accused of political bias (Moon, 2018) and journalism advocacy takes on a new focus. Given the relatively recent emergence of social media and abundant data on traffic and content, researchers might well address the contrast between gatekeeper and advocacy roles in mass communication.

CONCLUSION

Seen in the context of mass media and journalism, social media has become another bump in the road of unexpected competitors for traditional news of the later 20th century. While limitations of technology kept a focus on radio, television, and newspapers in the early years, the advent of cable TV, the Internet,

and social media has complicated the picture for both journalists and the audience. The shifting political and entertainment landscape presents a unique challenge for all participants, and one can only hope that social responsibility will prevail.

KEY TERMS AND DEFINITIONS

Advocacy Journalism: Journalism as critique and change agent (Thomas, 2018).

BBS: Bulletin board system.

Gatekeeper: Reporting information with scientific method for objective and valid results.

Mass Communication: A one-way flow from source to recipient.

Social Media: Communication portals where anyone can sign up and freely “post” messages to self-selected groups of individuals.

Breaking Fake News and Verifying Truth

11

ROIS, Japan

INTRODUCTION

How to distinguish between fake news or not? How to verify information whether it is true or not? The goal of this article is to review online fact-checking studies on fake news. The core of this matter is how to progress fact-checking on misleading information and vague knowledge (Viviani&Pasi,2017; Shao, et al., 2018; Vosoughi, Roy&Aral, 2018). This procedure is crucially managed by manually or some computational mechanisms. The burden of proof should be evaluated truthiness by scientific ways included objectiveness and falsifiability. It never accepts neither solipsism nor agitating manners. In addition, it should take carefully to extract the most importance from the truth whether it is manually or mechanically, and it also reconsiders those backgrounds. For sound democracy, mediated knowledge brings the facts for citizens, and it should encourage them to ponder their directions of governances in nation (DiResta,et al.,2019; Howard, et al., 2018). Using ICT, it should properly facilitate fundamental educations for them.

BACKGROUND

The world is the totality of facts, not of things (Wittgenstein, 1922). Fake news recently reminds us this renowned sentence. Wittgenstein also said that the world consists of a set of facts, and facts are determined by truth or false as a proposition style. He casted questions on world cognition, provable logics, facts and knowledge. However, to date, fake news and post-truth are too far from truth, facts, impartiality and fairness. Any assertions of fake news are never valid and those contents are almost based on malicious intentions or misunderstandings. Moreover, fake news can spread faster than other reliable information through social networks (Doer,Fouz&Friedrich,2012; Roozenbeek&Linden,2018).Especially, these mediated information which recognized as fake news can be found in the fields such as politics, medical health, socioeconomics, ethnicity, ideology, gender and other sensitive topics. Regarding populism, some governors demonstrate 'self-first' actions and they sometimes use it as political propaganda against their opponents (Bobo,2017; Lamont, Park&Ayala-Hurtado, 2017; Wang,Luo,Niemi&Li, 2017).

Lexically, Oxford dictionary defines 'post-truth' as "*relating to or denoting circumstances in which objective facts are less influential in shaping public opinion than appeals to emotion and personal belief*". And Nielsen&Graves(2017) identified types of fake news such as *satire, poor journalism, propaganda, some advertising and false news*. Similar concepts can enumerate stereotypes (Lippmann,1922), prejudice and rumor. Moreover it definitely claims that it also lacks falsifiability (Popper, 1963) and it seems a kind of solipsism of each claimant.

DOI: 10.4018/978-1-7998-3479-3.ch101

FOCUS OF THE ARTICLE

When borrowing Marx's proverbs, a specter is haunting the Worlds -the specter of fake news. All the powers of global communities have entered into a holy alliance to exorcise this specter. At 2nd Feb. 2017, AAAS (American Association for the Advancement of Science) held in an academic symposium for discussing the fake news and post-truth. As through social media, they argued that our contemporary society has vulnerability against verification on fact and credibility of information sources. And of course, Facebook, Twitter and other social media sites have already launched eligible regulations and managements in verifying submitted contents and fact-checking.

However, there will be a stumbling block against those objectives. Renowned mathematician Hilbert believed that all statements in mathematics can be proven as true or false. But please recall the fact on Turing Machine (Turing, 1937; Copeland&Shagrir, 2019). Similarly, revealing fake news seems possible, it is not easy tasks. Whereas our constraints are within finite calculation time and efforts, fake news has been growing steadily with enormous contents and its derivations added each day. Will it be possible to verify all of them within finite time? As Turing machine proved, it is hard to demonstrate certainly truth regardless of the limits of manpower or computer. For example, if one finds the fact that it is not fake news by verifying target statements (for example, from 1 to N) within each content suspected to be certainly fake news, however it cannot be concluded that all of them are true, just because such disproof is not found in that time. In the future, by adding $N + 1$, it might turn out fake news. Then, these verifications on the bases of inductive reasoning and 'evidence of absence' are still harder for us.

The goal is the very clear. In the context of finite space, computable and manageable constraints, the core of this matter is how to progress fact-checking on those fake information and uncomfortable knowledge online (Viviani&Pasi,2017; Shao, et al, 2018; Ciamapglia, 2018). Principally, breaking fake news is to distinguish between subjective belief and objective facts. The former is trust and belief in our cognitive system and it justifies our world of view. The latter is fact and evidence, and it shall stress on scientific verification and prioritized importance rather than public preferences for acceptances. And some reasons in fake news problems such as scientific process and human mental model as belief system makes it more difficult. Can be strict matching both truths between subjective and objective perspectives consistent with each other? As extracting only important things from worthless matters in massive online sources, how to evaluate the true fact in ordered by some confident prioritizations?

In brief, any fact-checking process requires decisively at least below methodologies. If and only if empirical verified evidences and its reexamination processes are ensured, it can be regarded as canonical manners of scientific knowledge.

1. *Experimental*
2. *Detection*
3. *Estimation*
4. *Collective*
5. *Third party Authentication*

Regarding these concerns, there are reasons systematically to study fake news. That is, there are some definitive categories to consider at least.

1. Verification of Fake News
 - i. Definition on Fake news or not
 - ii. Verification Methodologies
2. Ambivalence of Social Media
 - i. Recognition on Sharp power
 - ii. Education for Ordinary Citizens

SOLUTIONS AND RECOMMENDATIONS

Experimental

Experiment can be conducted as strong and decisive methodology for clear understanding on phenomena and facts (RAND Corporation, 2017). The burden of proof should be evaluated truthiness by scientific ways included reproducibility, objectiveness and falsifiability (Fanelli, 2018; Shiffrin, Börner & Stigler, 2018). It never accepts neither solipsism nor agitating manners. According to Sober (2008), data centered experimental researches which are based on inductive evidence and facts can be categorized as Bayesian and other schools. Generally, Bayesian School specifies their studies to model observer's objective probability and these conditional facts, and then it can be properly estimated updating certainty for true nor not.

Usefully, Bayesian statistics can also detect a subjective probability of each individual when it acquires post probability information as truth or falseness (Kahneman & Tversky, 1973, 2000). They demonstrated serial consequences by psychological experiments that many of subjects unintentionally and unconsciously evaluated higher subjective probability for a member of their belonging group (in-group) than other groups (out-group). These statistical significant evidences clearly were obeyed in formalization derived from Bayesian statistics. It was a well-known breakthrough for researches in cognitive biases, and behavior science and social psychological experiments repeatedly endorsed that human being is inevitably apt to neglect their undesirable information, and they are strongly committing to believe in their supportive one (Oakes, Haslam & Turner, 1994).

Here, there was empirically observation data obtained from USA president election campaign at 2016. Before this voting day, according to a report conducted by Pew Research Center (2017), two third of Americans got some news from social media including fake news. Further, for example, fake news: "Pope Francis shocks world, endorses Donald Trump for president, releases statement" was supported by three fourth (75%) of the total of Trump supporters, whereas his opponents were only 46%. It really exhibits in-group bias for interpretation consolidated with their political ideologies. If still yet, those who eagerly accept fake news such as delusional, anti-intellectual and anti-scientific believers may be still confused.

Detection

Detecting fake news clearly relates to AI studies on developing autonomous mechanisms such as logics, recognition, representation, knowledge and inference (Russel & Norvig, 2009). Especially, AI studies generated automatic classifiers of web contents, web crawlers, autonomous bots, and agent-based services online. As standing on general computer engineering as well as security (e.g. ISO/IEC JTC1/SC27), necessary features should be referred in employing fact-check systems on fake news contents (e.g. authenticity, accountability, non-repudiation, and reliability).

Recently, Shu et al. (2017) categorized characterizations of fake news as psychological and social foundations as well as malicious accounts and echo chamber. And they proposed several methodologies for fake news detections such as *knowledge-based*, *style-based*, *stance-based* and *propagation-based one*. In this case, there is necessary to prepare ontological database, corpus and knowledgebase in advance, and natural language processing is quite needed in massive text data.

Otherwise, there are varieties of online services such as detection of bots spreading fake news (e.g. *Distil Networks*), analysis on behavior pattern of site visitors, reputation management against fake news, dark-web monitoring and block-chain based credibility of information (e.g. *Userfeeds*). And Truelove et al. (2017) proposed the ways to validate fact check against posted contents by through Twitter and other similar online services. And they found the strong correlated relationships on objective confidence for media contents when third party readers offered confirmable facts such as witness information, supporting rate by other bloggers and attaching supplements of visual information (e.g. image or thumbnail files) with geotag data (Fang, Nourbakhsh, Liu, Shah & Li, 2016). However, to date, text formatted news (e.g. bot, short blog, news headline) are automatically generative by AI based technologies (Shao, et al., 2018). Then those generated information do not provide any confidence against the evidence of fake news yet (Schafer, Evert & Heinrich, 2017).

On the other hands, facial information employs a key factor in any interactive communications in daily life and speeches in politics. And image recognition technologies have recently advantages for evidence based communication system. In this concern, Wu, et al., (2018) has produced AI based deception detecting system. They articulated that their systems have approached to high quality for detecting deception of humans' vague facial expressions and motion captured data extracted from video clips. This approach may open the possibility for deception-less interactive communications.

However new technology has already encountered new vulnerabilities against computer security and anomaly. It is the very possible to lose the evidence for occurred events provided formats by video-clip and photo files using generative adversarial network (GAN) models in AI technologies (Goodfellow, Bengio & Courville, 2016). Deep learning is specified as pattern recognition of machine learning based on massive samples. In contrast, roughly speaking, GAN is defined to recreate and modify mathematically arbitrary image files (Li, Swersky & Zemel, 2015). Thus those automated artifacts as image files can be automatically regenerated by this model to match actual events, and this technique has been worried about effective abuse for alibi and counterfeit in fake news and political forgeries against antagonists. Thus those models have possibilities to critically damage blind spots in computer security using facial recognition system for identified authentication. As smart phone and other computational devices have equipped digital cameras, and ordinary people can attach their photo clips for identification to intercommunicate with each partner, but they can make facial deceptions each other. Online witness can also make any deceptions by photo clips regenerations. Moreover, according to empirical findings in brain sciences, trust for other individual is a fundamental for our sociality, but those cognitive and neural mechanisms were not well revealed. Feldman Hall, et al (2018) found that similarity of stimulus between trusted acquaintance and morphed face image was a critical factor for trustworthy. Can our human mind break those modified deceptions?

Estimation

In computational studies for verification on fake news, it should devote robust explanations standing on mathematical and statistical relevance. These researches needs to manage and analyze online big-data and these are still higher priority. Knowledge based reasoning (Hosseinmontlagh & Papalexakis, 2018),

natural language processing and machine learning can be diversified in these days. These fields in data science and computer sciences have varieties of statistical means for the purpose of fact checking and credibility evaluation on online contents (Hastie, Tibshirani & Friedman, 2009; Liu, et al., 2017; Shao, et al., 2018). And there are needs for tracing inter-documents' links structures, contents comparisons and analyzations in ontological semantic means.

At least, to evaluate observation and choose best fitting models for purposes, it enormously offers supervised and unsupervised learning (including deep learning), Bayesian model (including Bayesian networks), classification, regression models, neural networks, clustering, tensor model, random forest, support vector machine, genetic algorithm (Goldberg, 1989) and other mathematical models. In addition, social network analysis for social media can be useful to detect opinion groups between discussing site, and it can be possible to explore various factors of inter-group conflicts or mutual cooperation. And recently, sparse modeling and pattern recognition algorithms can contribute to detect and classify fake news. The former can accurately predict tendencies based on few samples (Mairal, Bach & Ponce, 2014), and the latter is to acquire specification for identifying data.

In practical cases, there are already many tools such as artificial intelligence based machine learning, data-mining, statistical algorithm and mathematical modeling (Pramanik, et al., 2017). And some studies produced automatic detection and monitoring systems against online contents such as fake rumors, hate speeches and agitations (Ratkiewicz, et al., 2011). In contrast, it launched a kind of counter-media to impress good facets of the facts. In this result, it will expect to decrease inter-conflicts and antagonism between individuals, groups and nations (Article 19, 2015; Garimella, et al., 2017).

Collective

Crowd and collective intelligence has been recognized as one of proper ways to verify evidence (Das & Magdon-Ismael, 2012). As one of comprehensive works, Viviani & Pasi (2017) has summarized research topics on these fields. For instance, they picked up various cases: (1) detecting opinion spams in review site, (2) the detection of fake news and spam in microblogging, and (3) the credibility assessment of online health information. To evaluate reliance of information, it should include verification on fact information itself as well as information sources. As they said, users' reliance for online information can be based on 'crowd consensus'. It recalls Wikipedia editing style. For the considerable ways of proofing truth online, they categorized (1) contents analysis, (2) users' behavior analysis, (3) linkage and graph structure analysis and (4) multiple ways.

In this concern, Facebook recently tackles these matters, practically, but manual and automatic hybrid checking are still hard for verification on credibility of contents. As statistical pattern matching and machine learning on the bases of the 'reliable knowledgebase' as past similar events and facts, the fundamental of contents verification is to be coincided with mutual consistency between true or false in each information sources. However these AI based mechanisms have weak points not to easily judge the truth on statistical rare cases and individual matters (e.g. hidden personal profile). For confident validation on such things, many of crowd based experts should take participation in those processes.

In political contexts, those who have common senses among journalists to do voluntary validation on fact check are collectively verifying political utterances and speech contents by government leaders and politicians. There are already various online grass-root activities for revealing fake news and post truth of propaganda such as *Politifact*, *Hoaxy*, *Snopes.com*, *FactCheck.org*, *The Washington Post Fact Checker*, *CNN Reality Check* and others.

Similarly, as academic peer review are underlying in collective participation of external experts (Hofmann, 2018), Price&Flach (2017) argued how artificial intelligence will be progressing crucially peer review. As mentioned above, peer review on academic papers is the very similar to fake news checking. Much misconduct in academics can be perplexed in enormous efforts, but it still requires manual and hard works (Steen,Casadevall&Fang, 2013). Using AI based review systems, it actually applies to various other contents. These mechanisms can also help for identifying fake news.

Third party Authentication

Particularly, ordinary citizens are often surrounded with fake news related to health information as well as politics, and then it should be critically reexamined by further investigations. For example, Viviani&Pasi (2017) also argued fake news on medical health knowledge in social media sites. And as mentioned above, they proposed survey-based fact checking approach by trustable authorities, opinion leaders and experts. This reason requires fact checking by higher expertise and quality assurances for online contents. But it consumes much time and costs.

Thus serial efforts by third party can offer authenticity of scientific knowledge and prevent further misunderstandings of pseudoscience. Crucially, in medical health cases, there are often significant issues not to be regarded as varieties of fake news, but it definitely denotes that scientific knowledge strictly requires convincing verifications. For example, as many clinical research findings could not be often reproduced, and then NIH (National Institute of Health, U.S.A) had already recommended that the results of significant findings should be revalidated (Ioannidis, 2005; Fanelli, 2018). These reasons are that some of them are consisted of the conditions under suspicious of forgeries or ambiguous results in examinations (Steen, et al., 2013). In other cases, accepted academic papers are not always endorsed by other authorities in scientific manners. For example, it can exhibit a case to recognize an importance of risk assessment against GMO (genetic modified organization) in 2012. A published paper reported that rats who had eaten genetic modified corn tended to die faster than other control condition (Séralini, et al., 2012), but it raised controversy on scientific verification claimed from the European Food Safety Authority (EFSA). As results of this dispute, EFSA concluded original revalidation for this evidence was inadequate. Namely accepted paper about the risks of GMO in academic journals was overturned by third party authority (Houllier, 2012).

Regarding these backgrounds, fake news distributors often abuse the difficulties for verification related to medical health as well as political information. Not without saying, it is also certainly to require credibility and transparency of reviewed information in those fact-checking site organized by third party (Brandtzaeg&Følstad, 2017).

FUTURE RESEARCH DIRECTIONS

Global Affairs against Media Manipulation and Sharp Power

Due to fake news and post truth by through social media, global society might be on the brink of democracy. The era of social media had already opened the Pandora box as the cyber war (e.g. sharp power or hybrid war) as well as communication tools for ordinary citizens. To date, the keys are that social media already becomes global networking with world opinion and contagions of influence across the border of the worlds. In this sense, those collective dynamics participating by ordinary citizens sometimes cause to

lose the order of their national governance and sound conditions in democracy. As famous evidences are recalled, 'Arab Spring' and similar events had outperformed their national governing regimes (Shibuya, 2017). In democratic societies, nevertheless those revolutions will not be usually happened, it should take close look at the nature of voting behaviors at elections campaigns (Shao, et al., 2018).

Regarding these conditions, citizens has blindly tendencies to believe in such information, which apparently accepted by collective followers online. Then it still remains vulnerabilities to confuse any evidences. Those who support mediated fake news desire to believe only self-regarding 'fact' and see 'fact' as they want are likely to organize their networking with like-minded partners ('echo chamber': Sunstein, 2001). Consequently, as social media empower vigorous networking by ordinary citizens and their numerous opportunities against political and ethnic opponents (Corner, 2017; Jost, et al., 2018), those cyber politics opened the door for emerging another types of public opinion formation (Choucri, 2012; Shibuya, 2017). They neglect both objective verification and sufficient fact checks on fake news, and further they will interconnect with like-minded partners and repel their opponents (Bakshy, Messing & Adamic, 2015). Gradually, this polarization among opinion groups apparently organizes their ideology as a part of the real world. In this way, when majority who eagerly desire to support extremist's demagoguery gains total legitimacy in whole democratic society, it will be time to encompass the political power by the name of the democracy. As result of this, their nation may lose a compass for governing direction.

As 'Arab Spring' and similar events showed, the most important was that those historical events and social movements against governing regime were collapsed by human-made dynamics (Gonçalves & Nicola, 2015; Jost, et al., 2018). These were complex factors, but it was not spontaneous accident. At that time, social media became as one of political ways for opinion manipulations. Inevitably consequences, using social media, for example, third parties (i.e. terrorists and antagonists) will be possibly to spread fake news, agitate public opinions, organize opinion groups and intrude to new similar events against opponent countries by their purposes.

These are obviously to inspire practical applications (Weinberger, 2011; RAND Corporation, 2017). In USA, NSF (National Science Foundation) published their press leases at 2015 that they launched the novel interdisciplinary research grants in computational and social sciences. Otherwise DARPA (Defense Advanced Research Projects Agency, USA) also pushes their intensive programs to progress studies in both academic and military purposes such as NGS2 (Next Generation Social Science) and SocialSim (the Computational Simulation of Online Social Behavior). And they stepped further to analyze massive data obtained from online social media and to examine it by social simulation.

Thus those researches will trigger to boost applied usages based on vigorous investigations for social media influences and toxicity of fake news against target countries' public opinion formation. Reversely it also spurs to motivate further researches on media control and defenses in their own nations, and it calls more similar studies.

Educations for Citizens

Here, during the age of the cold war, Morgenthau (1978) had forecasted our future of world conditions: when ordinary citizens harden their attitudes for nationalism and exclusionism by globally intermediated communication tools (global opinion or world opinion), with enthusiasm, it may become inevitably next world war in the future. His future is our time, and political demagogues in his era can be regarded as fake news in our time. His foretelling clearly said the negative facet of social media?

Democracy has been underlying in sound judgement and opinions among sovereigns (i.e. citizens). In the past, Machiavelli ironically said “*Though the populace may be ignorant, it is capable of grasping the truth*”. However, this phrase should be ignored at once. All of citizens do not have any methods to validate mediated vague information and defend their opinions, and they are easily influenced by other influencers. Political propaganda and opinion manipulations with exposing malice neglect those process itself, and fake news and post-truth are actually vanguards to perturb our sound understanding of entire knowledge (DiResta, et al., 2019; Howard, et al., 2018).

Therefore, using ICT, it should facilitate fundamental educations for ordinary citizens (Shibuya, 2006). Some countries legitimated strict regulation acts against extreme activities of spreading fake news. For the first step, as breaking fake news and critically thinking about agitations, ordinary citizens should be cultivated by themselves for own practical behavior based on the social common standard and rationality in whole society.

CONCLUSION

This article argued online fact-checking studies on fake news. The core of this matter was how to progress fact-checking on fake information and uncomfortable knowledge. Principally, breaking fake news is to principally distinguish between subjective belief and objective facts, and it shall stress on scientific important evidence rather than public preferences for acceptances. The burden of proof should be evaluated truthiness by scientific ways included objectiveness and falsifiability. It never accepts neither solipsism nor agitating manners. In addition, it should take carefully to extract the most importance from the truth whether it is manually or mechanically, and it also ponders those backgrounds. Using ICT, it should properly facilitate fundamental educations for ordinary citizens.

KEY TERMS AND DEFINITIONS

Fake News: Nielsen and Graves (2017) identified types of fake news such as satire, poor journalism, propaganda, some advertising, and false news.

Sharp Power: It originally refers to a variety of cyber warfare being operated by authoritarian powers using social media and ICT. It contrasts with hard power (military forces) and soft power (socioeconomic and cultural means).

Crossfire and Violation of Human Rights in Bangladesh: A Critical Review

11

Md. Awal Hossain Mollah

University of Rajshahi, Bangladesh

INTRODUCTION

This paper depicts the violation of human rights caused by law enforcing agencies in Bangladesh. The law enforcement agencies of Bangladesh are universally appreciated for their patriotic and courageous efforts to combat terrorism inside the country. The law enforcing agencies are mainly responsible for maintaining the law and order, protection of life and property of the citizens and prevention and detection of crime to establish rule of law in a state. However, the violation of human rights by the law enforcing agencies in Bangladesh has been increasing severely for the last few years. Why the protectors become perpetrators has also explored in this paper by highlighting the pattern of violations made by the law enforcing agency and their impact upon the law and order situation in Bangladesh. The existing legal framework of governing the law enforcing agency has also been critically examined and finally pinpoint some recommendations for the eradication of the pitfalls of security forces. The paper is qualitative in nature and case study on Bangladesh.

BACKGROUND

This section focuses on the major elementary issues and background of the violation of human rights in Bangladesh. Primarily, crossfire and violation of human rights was a media term in Bangladesh, however, now widely used to express the murder of a criminal or accused in a gunfight event between members of law enforcement agencies and criminal groups. It alleged by the media, opposition political parties and civil society that law enforcing agencies are pressured to get quick results, often with unofficial guarantees that they may use any means possible to accomplish the task at hand. This occurrence is facing enormous criticisms in the home and abroad and considered as a violation of human rights.

Human Rights

The definition of human rights is a debating issue but it has been discussing as a burning issue from time immemorial. Human rights are rights inherent to all human beings, whatever our nationality, place of residence, sex, national or ethnic origin, color, religion, language, or any other status. Every single citizen is equally entitled to human rights without discrimination (United Nations, 2016). Human rights, deprivation and unequal allocation of resources have been issues for then West Pakistan (now Bangladesh) between 1947 and 1971. The people of Bangladesh struggled for 23 years to ensure and establish their rights. In 1971, Bangladesh was independent but three million people lost their lives, ten million

DOI: 10.4018/978-1-7998-3479-3.ch102

fled across the border to India and 200,000–400,000 women were raped, leading to approximately 25,000 pregnancies (Linton, 2010:194). Could anyone imagine how brutally human rights are violated in Bangladesh? Though 47 years of independence have passed, however, violation of human rights is still continuing in Bangladesh. The country struggled to overcome significant barriers to the realization of human rights: a repressive police force, poverty, corruption, unequal distribution of wealth and opportunities, and a slow legal system. The state apparatus deliberately suppressed human rights, extraterritorial actors and the dynamics of regional and global hegemony allowed limited human rights for the people (Halim, 2010).

Rapid Action Battalion

In 2004, the government of Bangladesh introduced the elite anti-crime force called the Rapid Action Battalion (RAB) following a rise in the rate of crime in the country. The RAB was created through the “The Armed Police Battalions (Amendment) Act, 2003,” and published in the Bangladesh Gazette of July 12, 2003. The primary tasks of the RAB were to maintain internal security; recover unauthorised arms, ammunition, explosives and other such articles; apprehend armed gangs of criminals; assist other law enforcement agencies in the maintenance of law and order; gather intelligence; investigate any offence concerning the government; and, any other such duties as the government requires from time to time. Seconded members from six services such as the Bangladesh Army, Bangladesh Navy and Bangladesh Air Force, the Bangladesh Police, and members of Bangladesh’s other law enforcement groups such as Border Guard Bangladesh and Bangladesh Ansars joined the RAB (Human Rights Watch, 2011). This force has been accorded with special power with special salary and benefits package. They are better equipped than the regular police force. For example, in order for them to arrive at the crime scene fast, they are given a helicopter.

Crossfire and Extra-Judicial Killing:

The term ‘crossfire’ is synonymous of the term ‘death in an encounter’ which is used by law enforcement agencies in Bangladesh. The government justifies the killings by using the term “crossfire,” which it refers to as gunfights between any alleged criminal group or terrorist and the RAB or police (Habib, 2016). The term ‘extrajudicial killing’ means killing someone without following the legal justice system, laws, and constitution (Kamruzzaman, Khan, and Das, 2016). Killings committed outside the judicial process by or with the consent of public officials, other than as necessary measures of law enforcement to protect life or as acts of armed conflict carried out in conformity with the rules of international humanitarian law is called extrajudicial killing (Rodley, 2009). Such killings are prohibited by Bangladesh’s Constitution and national laws, as well as by various international instruments that Bangladesh has ratified. However, the extrajudicial killing has been made an integral part of the law-enforcement system of Bangladesh for many years by “crossfire” or “encounter” with few other synonyms like “gunfight”, “in the line of fire” etcetera (Kamruzzaman, Khan, and Das, 2016). The overall human rights situation in Bangladesh is still at an alarming level in the first six months of 2018 due to a rapid increase of extra-judicial killings, a high number rapes and sexual assault of women and custodial deaths across the country.

FOCUS: STATUS OF HUMAN RIGHTS IN BANGLADESH

This part analyses the main text of the chapter under following sections.

Legal Framework of Human Rights in Bangladesh

Bangladesh has ratified all the major international human rights instruments such as the International Covenant on Civil and Political Rights, 1966 (ICCPR) (Article 6, 7, 9, 10) (Momtaz, 2013). International Covenant on Civil and Political Rights, 1966 ensures that no one shall be subjected to torture, or to cruel, inhuman or degrading treatment or punishment. The Convention Against Torture (CAT), Convention on the rights of the Child (CRC), and the Convention on the Elimination of All Forms of Discrimination Against Women (CEDAW) (ASK, 2015). Bangladesh is a party to the Convention against Torture and Other Cruel, Inhuman or Degrading Treatment or Punishment (CAT), which stipulates that State Party shall ensure that all acts of torture are offenses under its criminal law (Momtaz, 2013). The same shall apply to an attempt to commit torture and to an act by any person which constitutes complicity or participation in torture (UNDP, 2002).

Torture by public officials date back to the period immediately following independence, and it appears that torture has become institutionalized, a practice that is perpetrated regardless of the government in power; there are only fluctuations in the nature of the torture practices and in the scale (Amnesty International, 2000). However, the constitution of Bangladesh also outlaws any form of torture (ICG, 2009). The Universal Declaration on Human Rights (UDHR) (art. 3, 5, 7, 8, 9, 10, 11) is considered as the jus cogens throughout the world from which no derivation is possible. Still 'torture' has not been defined as a crime in Bangladesh (Momtaz, 2013). However, there are a number of reservations has been made by Bangladesh which made it ineffective and denies the equal status of women. Bangladesh reserved article 14 of the Convention against Torture which states "Each State Party shall ensure in its legal system that the victim of an act of torture obtains redress and has an enforceable right to fair and adequate compensation, including the means for as full rehabilitation as possible (Momtaz, 2013). In the event of the death of the victim as a result of an act of torture, his/her dependents shall be entitled to compensation. Therefore, the implications for this reserve are to deny such compensation or rehabilitation and also invalid the constitutional mandate under Article 35 (5) of the People's Republic of Bangladesh (United Nations, 2016). The International Covenant on Civil and Political Rights (ICCPR) which was ratified by Bangladesh in 5th September 2000 ensures that every human being has the inherent right to life and that this right should be protected by law and no one shall be arbitrarily deprived of his life (Momtaz, 2013). The Bangladesh Constitution also provides provisions to ensure human rights.

The Constitution of Bangladesh has been grunted 18 fundamental rights by Articles 27 to 44. Articles 31 and 32 guarantee the right to life and personal liberty and it is applicable to both citizens of Bangladesh and foreign nationals (Habib, 2015). Article 33, provides that the arrested person must be produced before a magistrate within 24 hours excluding the time of journey from the place of arrest to the court of the magistrate.

The HCD of Bangladesh held that the detention of prisoners in Jail after they have served out the sentences is a violation of their fundamental rights guaranteed in the Constitution, especially the right to life (Law Help Bangladesh, 2016; Momtaz, 2013). Hence, through this judicial activism, there is scope for a post-trial concession to enjoy by a prisoner who has spent in custody for a considerable time (Momtaz, 2013).

The constitutional guarantee of the right to life – the right not to be deprived of life is given in accordance with the law and cannot be suspended or derogated from under any circumstances (Habib, 2016). However, in earlier years, state security forces reportedly continued to be responsible for extra-judicial killings in the form of cross-fire deaths, death in encounter/encounter killings and custodial killings Momtaz, 2013). These incidents have become so frequent that a new term has been coined in the country: death by crossfire. Currently, the most significant human rights problems are enforced disappearances. Human rights groups allege the involvement of the country's security forces (United States Department of State, 2012).

LAW ENFORCING AGENCIES IN BANGLADESH

In Bangladesh, as a law enforcing agency we have the 'police force'. The year 2004, three special units were formed to help the regular police. These are:

- Rapid Action Battalion
- Cheetah; and
- Cobra.

For the better understanding of our discussion, the legal basis of our law enforcing agencies is given below:

Bangladesh Police Force

Queen Victoria has ascended the throne of this Indian Subcontinent in 1858 and during her reign the Indian Police Act, 1861 was enacted (Momtaz, 2013). And the existing police force as an organized department was established during the British rule in 1861 through the promulgation of this Police Act (Act V of 1861). Although there have been a few amendments while it was renamed the Police Regulation of Bengal or PRB, the Act has virtually remained the same in spirit and still in force after almost 150 years (Momtaz, 2013).

Rapid Action Battalion

The Rapid Action Battalions (hereinafter 'RAB'), the elite force was created through 'the Armed Police Battalions (Amendment) Act, 2003 and published in the Bangladesh Gazette of July 12, 2003 (Habib, 2016). The RAB is a composite force, manpower wise, because section 3(5) of the law states: 'Notwithstanding anything contained in this Ordinance or in any other law for the time being in force, armed personnel and officers in Rapid Action Battalion may, as and when necessary, be appointed on secondment or deputation as the case may be, from among the persons who are in the service of the Republic, including any discipline force' (Kamruzzaman, Khan, and Das, 2016). It is a hybrid force consisting of the police and the army. Momtaz (2013) mentioned that The Amended Armed Police Battalion ordinance has given birth to:

- Armed Police Battalions,
- Rapid Action Battalions.

- internal security duties,
 - a. recovery of unauthorized arms, ammunition, explosives and such other articles as the government may, from time to time direct,
 - b. the apprehension of armed gangs of criminals,
 - c. assisting the regular law enforcing agencies including the Police for maintaining law and order, and such other duties as the government may, from time to time, assign.

In addition, Cheetah and Cobra were formed as special units of the detective branch. They also enjoy a lot of impunity in arresting people (Momtaz, 2013). We have, also Border Guard of Bangladesh (BGB), Industrial police, Highway police, CID, SB, 11 Training institutes, 6 Metropolitan Police, 7 Range, Railway Range, the Special Women Police Contingent (SWPC) established in 2008, and Police Hospital.

THE LAWS IN QUESTION AND HOW THEY ARE MISUSED?

Section 54 of the Code of Criminal Procedure

Under section 54 of the Code of Cr. Pc. 1898, individuals may be arrested under suspicion of criminal activity without any order from a magistrate or a warrant (Momtaz, 2013).

4.2 Section 100/86 of the Dhaka Metropolitan Police Ordinance Momtaz (2013) mentioned that Section 86 of the Dhaka Metropolitan Police (DMP) Ordinance provides:

If any person is found in the following situations during the period between sunset to sunrise:

- Equipped with dangerous machinery without satisfactory reasons, or
- Covered face or in disguise without satisfactory reason, or
- Present in any residence or any other building or any boat or water vessel or any other transport without satisfactory reason, or
- Sleeping or wandering on any street or in any place without satisfactory reasons, or
- Possessing the tools of entering any house forcefully without satisfactory reason, then the person will be liable for one-year imprisonment or fine of taka two thousand or both.

Section 100 of the DMP ordinance provides: in the presence of any police officer or in his attention if any person commits an offense under this Ordinance or any other law in force, that police officer can arrest him without a warrant.

The Special Powers Act 1974

The Special Powers Act 1974 (hereinafter SPA) is deemed by human rights activists and other members of civil society as a repressive law (Kamruzzaman, Khan, and Das, 2016). The use and abuse of this Act in the name of protecting the security of the state has resulted in a steady pattern of human rights violations. The Act provides 'Special Measures' for the prevention of prejudicial activities, for a speedy trial and punishment for grave offenses (Momtaz, 2013). Momtaz (2013) mentioned that under prejudicial acts, the law includes acts that are prejudicial to:

- the sovereign and/or state; to the maintenance of friendly relations between other states and Bangladesh;
- to the security of Bangladesh;
- to the safety or maintenance of public order;
- to the peaceful co-existence among different classes and section of the community;
- to the maintenance of law and order;
- to the security of any section of the public;
- to the economic and financial interests of the state;

For aforesaid grounds police can arrest any person at any time.

CROSSFIRE AND VIOLATION OF HUMAN RIGHTS IN BANGLADESH

The term “death in an encounter” is used in other countries which mean “crossfire” by law enforcement agencies in Bangladesh. The evil connotation associated with the word demonstrates the utter powerlessness of the people facing extrajudicial killings that are taking place in Bangladesh (Habib, 2015). The overall human rights situation in Bangladesh remained at an alarming level in the first six months of 2018 due to a sharp rise in cases of extra-judicial killings and custodial deaths, and a high number of cases of rapes and sexual assault of women across the country. A report published by the Daily Star disclosed that a total of 275 people have been killed during incidents of ‘gunfight’ and ‘crossfire’ with law enforcers, in custody of law enforcement agencies, or being shot by law enforcers, while 427 women were raped across the country between January 1 and June 30, 2018 (Daily Star, June 2018). The human rights monitoring report of Odhikar published in December 2018 mentioned that 456 people have killed extra-judicially by law enforcement agencies and 83 others were forcibly disappeared across the country by 11 months. Out of the 449 people were killed by crossfire (Odhikar, 2018). Besides, violation of human rights happened in various forms such as- death in Jail(64), political killing (79) and injured (3826), rape (619), killing by BSF (10), acid violence 26 and so may (Odhikar, 2018). The following table-1 represents the statistics of crossfire happened from 2001- to 2018 by various law enforcing agencies in

Table 1. Statistics of Crossfire 2001-2018

Crossfire/Gunfight from 2001-2018																	
Year (s)	RAB	Police	RAB- Police	Joint Force	Cheetah- Cobra	Army	BGB (Former BDR)	Police- BGB	RAB- Coast Guard	RAB-Police- Coast Guard	Coast Guard	DB Police	Forest Guard	Police- Coast Guard	Ansar	BGB- RAB	Grand Total

Total	936	1167	59	25	4	6	5	4	15	3	17	26	1	15	1	2	2286

Source: Odhikar Report June 2018. Statistics of Crossfire 2001-2018, http://odhikar.org/wp-content/uploads/2018/06/Statistics_Crossfire-Gunfight_2001-May-2018.pdf

Bangladesh. The table indicates that a total number of crossfire incidents happened 2286 by 18 years in which 1167 by police and 936 by RAB. It has been displayed by the table that in 2001 the violation of human rights by crossfire was zero but it reached 216 in 2017. The highest number of crossfire happened in 2005 which was 340. Though the number fluctuates but the crossfire incidents of the first 6 months of 2018 were 216 and at the end of December 2018 it reached number 449 which indicates the trend of crossfire and extrajudicial killing is increasing (Odhikar, 2018).

Bangladesh Prime Minister vows to continue anti-drug operations and over 120 people have been killed by crossfire and at least 10,000 arrested since May 14 to May 2018 by the Bangladeshi police (Arab News, 2018). This is a grave violation of human rights and a serious threat to human rights. Therefore, it has been proved that the arbitrary and abuse of power exercise by law enforcing agencies is increasing recklessly. This is the sign of lack of accountability, rule of law, good governance and deteriorating law and order and violation of civil rights in Bangladesh.

Though Bangladesh has ratified major legal instruments of International Humanitarian laws and the Constitution of Bangladesh enumerate the essential rules for protecting human rights, however, human rights always violated in various forms. Some are analyzed below. Annexes-1,2,3 and 4 shows the statistics of various forms of human rights violations till December 2018 in Bangladesh.

Death in Custody

Custodial death becomes a common happening for quite a long time. The word ‘custody’ implies guardianship and protective care. No civilized law permits custodial torture that springs out of a vicious desire to cause suffering when there is no option of any reprisal. Jails are overcrowded beyond capacity, as a result of arrest operations carried out to suppress opposition political parties and dissenting voices. The actual number of inmates is about three times more than the prisons’ capacity. The total capacity of prisons across the country is 36,614, but there were 92,404 inmates as of 30 November 2018. Many inmates allegedly die in jail due to the lack of proper treatment facilities and negligence by prison authorities. In November 2018, seven persons died in jail due to alleged ‘illnesses’. In *Jatiyo Mahila Ainjibi Samity vs. Bangladesh and Others* (criminal), the High Court held that detention in safe custody against the will of a detained person was illegal.

Many police officers believe that information or confessions cannot be extracted without physical threat or torture. That is why, although torture is prohibited under the law, its practice is rampant particularly under the ‘remand’. The form of torture includes beating on the soles of the feet, hanging, and suspension by the arms while they are tied behind the back, suspension upside down, beating, electric shocks, and psychological forms of torture including humiliation, threat, and insult etc. The Bangladesh Penal Code, 1860 has provided definitions and penalties for some offenses which very narrowly cover the area of torture as follows: offence affecting life (Section 299-311); hurt (Section 319-338A); to wrongful restraint and wrongful confinement (Section 339-348); offences relating to criminal force and assault (Section 339-358); offences relating to rape (Section 375, 376).

When such offenses are caused by the members of the police force, complains of torture can be brought against them under these provisions.

Very often it seems that torture is committed on a person on the orders of ‘higher-ups’ which allows police to act with impunity. The lack of disciplinary action against law enforcement personnel remains one of the main attributing factors of torture. Similarly, they should be instructed that any other forms of sexual abuse may constitute torture or cruel, inhuman or degrading treatment and that offender will be brought to justice’.

While addressing the protection against torture and degrading punishment under Article: 35(5) the HCD in *Alhaj Yousuf Ali vs. The State* asserted against the police torture and spoke of duty on part of the police not to exercise their power of arrest capriciously and fancifully. Torture for extracting any kind of confession would neither be right nor just nor fair’.

Arbitrary Arrest and Detention

Another form of human rights violation is arbitrary arrest and detention. In *BLAST and others vs. Bangladesh and others* [‘Section 54 Guidelines Case’, or ‘Rubel Killing Case’ or ‘Guidelines on Arrest and Remand Case’], the High Court recommended the some directives in exercising power under section 54 and 167 of the Cr Pc, 1898 and section 33 of the Special Powers Act 1974. Few can be mentioned here.

1. No Police officer shall arrest anyone under Section 54 for the purpose of detention under Section 3 of the Special Powers Act, 1974.
2. A police officer shall disclose his/her identity and show his/her ID Card on demand to the person arrested or those present at the time of arrest.
3. The police officer arrested under Section 54, or the Investigating Officer taking a person to custody or the jailor must inform the nearest Magistrate about the death of any person in custody in compliance with these recommendations
4. The Magistrate shall inquire into the death of any person in police custody or jail as per the recommendations. Later on in *Saifuzzaman vs.State* addressing Article 33 and Article 35(5), more guidelines have been issued regarding the police behavior while arresting a person as follows:
5. The police officer making the arrest of any person shall prepare a memorandum of arrest immediately after the arrest and such police officer shall obtain the signature of the arrestee with the date and time of arrest in the memorandum.
6. Time and place of arrest and the place of custody of the nearest relative or to a friend of the arrestee. An entry as to the ground of arrest and name of the informer must be made.

However, arbitrary arrest and detention are still continuing all over the country. On 8 November 2018, police arrested some people in the name of recovering drugs in Matikumra Village under Jhikargachha Upazila in Jessore District. Later the police inflicted torture on two persons named Faruk Hossain and Ashraful Islam and shot them in their legs. Faruk and Ashraful were admitted to the National Institute of Traumatology and Orthopaedic Rehabilitation in Dhaka. Dr. Ashim Ghosh said that the left legs of both Faruk and Ashraful had to be amputated. See pictures (annex-3).

Enforced Disappearance

The enforced disappearance of persons has been practiced since the mid 20th century. Enforced disappearances constitute an extreme violation of human rights, infringing many fundamental rights. Furthermore, not only is the person affected who becomes the direct victim, but also his or her family, colleagues, and friends as well as society as a whole. Most of the disappeared are persons who are critical of their governments. According to Odhikar Report (December 2018), in November 2018, 12 persons were allegedly disappeared after being picked up by members of law enforcement agencies. Among them, three were showed arrested after a few days of disappearance and the whereabouts of nine persons remain unknown. A highly visible and worrying number of enforced disappearances have been committed during the current

government reign. Opposition parties have expressed their concern and fear that there are possibilities that leaders and activists of the opposition will be disappeared in the lead up to the upcoming national elections. Many leaders and activists of the opposition parties, particularly the BNP, became victims of enforced disappearance before and after the controversial 10th Parliamentary elections in 2014. Of them, many have still not returned. The International Federation for Human Rights, Asian Federation against Involuntary Disappearance and its local member Odhikar has already urged the Bangladesh government to ratify the International Convention for the Protection of All Persons from Enforced Disappearances.

Police and Children

Children are also a victim of police's cruel behavior. In times of political unrest, children are used for throwing explosive substance and stones. That is why police always have a tendency to arrest children under S/54 and S/86 Dhaka Metropolitan Police Ordinance. In the Code of Conduct for Dhaka Metropolitan Police as to the responsibilities of the guard with the children, it is laid down that, 'Children will have to be behaved with soft words and in affectionate manners.'

As to the responsibilities of the officer-in-charge, the said Code cited that, 'in case of children or adolescents, officer-in-charge will behave with them with a vascular affection.' Many of the police stations in Dhaka city do not have separate custody room for children or female detainees. They are put in a police cell with adults and common criminals, which is, in total contravention with the Jail Code and the Children's Act' 1974. Very often after the arrest, what police doing is that they have not recorded the actual age of the children or mentioned extended age.

Under the ICCPR, children are generally considered to be individual' that enjoy the full range of rights under the covenant. Article 10(3) requires the separation of 'juvenile offenders'. But all these provisions are not ensured in Bangladesh.

Violence Against Journalists

At present, a number of journalists faced torture, threats or harassments from law enforcement agencies, (gangsters), government officials, or the student wings of various major political parties as noted in the table-4(Annex-4). Journalists are now very proactive to disclose everything before the public. That's why the government and political elites are suppressed them under recently crated laws in the name of yellow journalism by law enforcing agencies.

PROBLEMS, SOLUTIONS AND RECOMMENDATIONS

Why such violations are rampant in Bangladesh security forces? Numerous causes are responsible for such violations discussed with solution below:

Combating Corruption

Our police department has been charged against involving in corruption. Taking bribes, harassing innocent people, links with notorious gangsters, extortions, misusing power for personal gains are some of the common forms of crimes police are accused of (Momtaz, 2013). According to the report of the Transparency International Bangladesh (TIB), Corruption Perception Index (CPI), the law enforcement

agency is found the most corrupt sector in 2017 (TIB, 22 February 2018). Therefore, law enforcing agencies should be under accountability to combat corruption. Anti corruption commission may play a vital role in this case.

Salary Structure of Law Enforcing Agencies Should be Rational

The salary structure of the police department was comparatively so poor that it was simply impossible to lead an honest life. As a result, law enforcing agencies involved with a bribe and contract money and does any kinds of criminal activities. For example- the commanding officer of Rab-11 in Narayanganj Lt. Col. Tareque Sayeed Mohammad and the then company commanders Maj Arif Hossain and Lt. Commander Masud Rana of the RAB contract with Tareque is the son-in-law of Disaster Management and Relief Minister Mofazzal Hossain Chowdhury Maya. They abducted Seven people, including NCC panel mayor Nazrul Islam and senior lawyer Chandan Sarker, from the Dhaka-Narayanganj link road on April 27, 2014. Later, their bodies were found floating in the Shitalakkhya river (The Daily Star, 23 August 2017). Though recent pay scale and other facilities provided by the government (Hasina, 2014-onward) is very handsome (Basic 8250-78000) determined by National Pay Scale 2015 for the lowest to the highest level of Police officers. However, bribe or contract money still prevailing law enforcing agencies and act as a cause of crossfire and extrajudicial killing. Therefore, the salary structure should be rational based on market price of daily life.

Need Human Rights Training

One of the pitfalls lies with the existing training facility of the police. The amount of training of police officers in police stations, compared to training received at headquarters, is very low (Momtaz, 2013). A survey on the training of 100 constables of Dhaka Metropolitan Police, selected at random, who had completed 20 years of service, revealed that 96 received only basic training for 6 or 3 months (Momtaz, 2013). The basic cause is heavily biased towards physical training. Of 1,329 classes during a 6-month basic course, only 530 were devoted to academic training, and this was mostly on laws and procedures (1996). "In Bangladesh, there is no such institute for police where international standard education and training for improving overall human rights knowledge and capability of the police officers and training focusing on human security issues of the poor, woman and children can be imparted (Momtaz, 2013). As a result, of absence and ignorance, protecting and promoting the universal norms of human rights, police itself, become the perpetrators and human rights, violators.

Need Adequate and Healthy Accommodation

Accommodation is another big problem according to PRB, only 20% of the constables and sepia are allowed to live with their families (Momtaz, 2013). Others have to live in the thanas or barracks. A recent survey of accommodation by police headquarters revealed that 14,153 constables/ naiks/ head constables did not even have barrack accommodation (Momtaz, 2013). There were 32,454 cases of shortages of family accommodation for assistant sub-inspectors / head constables /naiks / constables; 4,603 for sub-inspectors and equivalents; 1,285 for senior assistant police superintendents/ assistant police superintendents/ inspectors and 98 for superintendents of police/ additional/ superintendents of police (Momtaz, 2013). Inside the dingy quarters, policemen sleep on the floor in very little space sharing

pillow and blankets. Then it is really a question of how they are to be conscious of human rights when they themselves are receiving inhuman treatment.

Recruitment Procedure Should Be Faire and Transparent

‘There is also a huge flaw in the recruitment procedure, which has far-reaching effects on the entire department. In this system, the field level officers do not have the opportunity to be promoted to the highest office in the department (Momtaz, 2013). Most of the higher level posts are exclusively set aside for officers who are appointed through the BCS Examination and start as an ASP (Momtaz, 2013). This is a strange procedure practiced in our country. This discriminating practice gives rise to frustration among the field level officers. Another important thing is that, in selecting a candidate political affiliation, good connection or how far the bribe becomes the deciding factor. By recruiting a police officer through pay off, the first thing he learns is corruption (Momtaz, 2013). So, recruitment process should be faire and transparent.

Legal Enforcement is Essential for law Enforcing Agency

There is no separate authority or department to investigate the human rights violations related to crimes committed by the police. As a result, it is the police which investigate allegations of human rights violations committed by their departmental fellow colleagues by which in most of the cases police get relief from the allegations or are awarded comparatively light punishment (Momtaz, 2013). The Armed Police Battalions Ordinance, 1979 laid down that no suit, prosecution or other legal proceedings shall be against any member of the Force, for anything which is done or intended to be done in good faith under this Ordinance (Habib, 2016). ‘That is why there are overall despair and dissatisfaction against the police so much that people are usually reluctant to report crimes in Thana as they deem sure that they will not get relief or fair treatment. No one is above the law, so police should be under control the law and judiciary.

Strong Political will

Members of the law enforcement agencies are enjoying impunity as the government is using them to suppress its political opponents (Momtaz, 2013). As a result of such impunity, allegations of harassment, torturing people, taking bribes, shooting in the legs, attacks and unlawful detention of the opposition and dissenters and extortion, were found against members of law enforcement agencies (Momtaz, 2013). The Torture and Custodial Death (Prevention) Act, 2013 was passed after relentless demands from human rights defenders. However, a vast majority of the torture victims and family members are not able to file any cases under this Act due to fear of reprisals; and those cases that have been filed are yet to see light in the court (Momtaz, 2013). Therefore, attitude of ruling political parties should be changed and at the same time strong political will is essential to punish the offenders.

CONCLUSION AND FUTURE RESEARCH DIRECTIONS

There is no doubt that Bangladesh police has been contributing to the law and order situation in Bangladesh. However, some controversial activities are ruining the image of this force. There are hundreds of allegations against the elite force officials for being involved in extortion, abduction, extrajudicial killing

by crossfire, rape and dealing in drugs and weapons. Some of the members of the RAB use organized blackmailing rackets to trap innocent people and finally extract money from the victims through various excuses. There are allegations that the law enforcing agencies have been politically used by successive governments. As discussed above those constitutional provisions says arrestees detained should be produced before the court within 24 hours after arrest. In practice, however, during the detention arrestees are not allowed to meet with anyone.

Governments and politicians have used the Bangladesh Police to destroy political enemies (ICG, 2009). It is most important that democracy is reinstated in Bangladesh but the free, fair, credible and participatory election is absent. Besides, active and participatory parliament is essential first which is lacked in Bangladesh. Accountability of government is important to establish the rule of law and good governance but all the mechanisms of accountability are under the government. Press freedom should be ensured and sufficient space should be granted for growing civil society but which is still under government control. Laws have greater permanence than commands which are also absent. The supremacy of laws ensures no person can claim to be above law but everything is strongly guided by the government. There cannot be a more undesirable situation where security forces, created for the purpose of providing safety to the people, would come to be considered by many as a source of their insecurity. Prescriptions to overcome these pitfalls are given below:

- First, we need to ensure free, fair, credible and participatory election.
- Human rights should be given the highest priority and this information has to be passed on to every single citizen.
- Parliament should be viable, vibrant, active and participatory.
- Mechanisms of accountability of law enforcing agencies and the executive branch should be more effective and free from government control.
- The culture of impunity must be seized from the existing system.
- It is to ensure that no one is above the law.
- Crossfire is not the solution to any kinds of criminal activities.
- The consciousness of people and moral education is essential for every sphere of our life.
- Lack of trust and conflicting attitude from and among political parties should be driven out.

KEY TERMS AND DEFINITIONS

Crossfire: The term ‘crossfire’ is synonymous of the term ‘death in an encounter’ which is used by law enforcement agencies in Bangladesh.

Death in Custody: Death in custody is a death of a person in the jail, in prison or custody of the police or other government law enforcing authorities.

Enforced Disappearance: In international human rights law, a forced disappearance (or enforced disappearance) occurs when a person is secretly abducted or imprisoned by a state or political organization, or by a third party with the authorization, support, or acquiescence of a state or political organization, followed by a refusal to acknowledge the person’s fate and whereabouts, with the intent of placing the victim outside the protection of the law.

Extrajudicial Killing: Extrajudicial killing is the killing of a person by governmental authorities, law enforcing agencies or individuals without the sanction of any judicial proceeding or legal process.

Human Rights: Human rights are rights inherent to all human beings, whatever our nationality, place of residence, sex, national or ethnic origin, color, religion, language, or any other status. Every single citizen is equally entitled to human rights without discrimination (United Nations, 2016).

Law Enforcing Agencies: In Bangladesh law enforcing agencies includes, Police, Army, Border Guard of Bangladesh (BGB), Industrial police, Highway police, CID, SB, 11 Training institutes, 6 Metropolitan Police, 7 Range, Railway Range, and the Special Women Police Contingent (SWPC).

RAB: Rapid Action Battalion (RAB) is an elite force created through the The Armed Police Battalions (Amendment) Act, 2003 to control crime in Bangladesh.

APPENDIX 1

Table 2. Statistics of Human Rights Violations: January-November 2018

Type of Human Rights Violation			Jan.	Feb.	Mar.	April	May	June	July	Aug.	Sept.	Oct.	Nov.
Extrajudicial Killings	Crossfire		18	06	17	28	149	50	69	24	35	19	34
	Shot to death		1	1	0	0	0	0	0	0	0	0	0
	Torture to death		0	0	1	1	2	0	0	0	1	0	0
Total			19	7	18	29	151	50	69	24	36	19	34
Enforced Disappearances			6	1	5	2	1	3	5	5	30	13	12

Source: Odhikar's Human Rights Monitoring Report on Bangladesh January to November 2018. Retrieved from: http://odhikar.org/wp-content/uploads/2018/12/human-rights-monitoring-report-November-2018_Eng.pdf

The above-mentioned data disclosed the overall picture violation of human rights caused by various ways including by law enforcing agencies by 11 months in Bangladesh. Though Bangladesh now improving the economic conditions progressively day by day the situation of rule of law, human rights, and democratic practice are deteriorating by an alarming rate.

Politics and Ethics and a National Framework to Combat Corruption in Zimbabwe

Tawanda Zinyama

University of Zimbabwe, Zimbabwe

INTRODUCTION

One of the issues which have pre-occupied the minds of researchers in Zimbabwe has always been the issue of governance and corruption. This is because governance defines the nature and outcomes of the relationship between the governors and the governed. If it follows the dictates of good governance, it brings joy to the governed, but if it is inspired by bad politics, it leads to the suffering of the people. Evidence of declining public trust has been seen in negative perceptions of the government as an institution prone to corruption (Zinyama, 2018). Rebuilding trust is critical to Zimbabwe in improving governance, public administration, combating corruption and reconnecting the citizens with the government. There is, therefore, an urgent need to come up with viable blue-prints for good governance Zimbabwe. This paper seeks to interrogate issues of politics and ethics because they have a bearing on the realisation or lack thereof of the Zimbabwean Vision 2030. In addition, this paper comes at a time when the government has already outlined its vision which clearly stipulates that Zimbabwe must become an upper-middle-class economy by 2030. This paper, therefore, seeks to provide strategies that can be employed to realise Zimbabwean Vision 2030.

The paper has four sections. Section one presents the background and conceptual framework where ‘man in the state of nature’, corruption, politics and ethics are operationalised. Section two focuses on the Zimbabwean anti-corruption system and experiences. In addition, the anti-corruption initiatives are presented and discussed such as public finance management reforms, ease of doing business reforms, electronic-government, anti-corruption structures, biometric measures, and lifestyle audits and public declaration of assets among others. Section three discusses the solutions and recommendations that can be employed to improve the institutionalisation process for anti-corruption such as ease of doing business, corruption and public procurement, reforming public sector management and fiancé, ending impunity, citizen empowerment, whistleblower protection and creating strong institutions among others. The last section presents the conclusion which concludes that corruption is a multifaceted issue that pervades all aspects of the public and private sectors, and cannot be addressed through legal reforms and enforcements without tackling the underlying causes and incentives for corruption. Hence, the need for a holistic revision of the national integrity system.

BACKGROUND AND CONCEPTUAL FRAMEWORK

It is the argument of this paper that corruption can be effectively contained after comprehending the human behaviour. It is important to start by discussing the state of nature of human beings in order to deduce the ethical and political perspectives that form the environment upon which corruption thrives.

Man in the State of Nature

One of the questions that preoccupy the philosophers and political thinkers' minds is: what is man – angelic or devilish? Assuming that there had been not powerful institution to administer and control human beings, in such a case what would have been people's behaviour toward one another? Would they have mutually respected and observed their rights or would they, like wolves, have fallen on and torn one another apart? Any sort of answer to this question necessitates the existence of a specific political and educational system. If one says that human being is intrinsically iniquitous, in that case he/she inevitably needs to perpetually control individuals. If one declares that human beings are innately angelic, it follows that he/she removes all restrictions and limitations and set them free. In order to comprehend corruption well, there is need to interrogate the views of two great thinkers. Hence, this section engages the viewpoints of Thomas Hobbes especially his famous statement, "Man is the wolf of other man." Subsequently, the section explores the views of Jean-Jacques Rousseau regarding human nature.

Thomas Hobbes' Views

Thomas Hobbes (1588-1679) is an English political philosopher who sought to apply rational principles to the study of human nature. One of the key concepts of Hobbes is the expression, "*Man in the State of Nature*", that is a hypothetical state wherein there is no political institution and administrative organisation existing in the society, the people being left to their own business and to do whatever they like. Since the instinct of love and defense of one's self is very strong in everybody, the people would be at each other's throats and would destroy one another. In the state of nature in which everybody is his/her master, one is at odds with the others concerning the nomenclature of things, and it is these differences that give rise to disputes and conflicts. Life in such a society is very thorny, painstaking and hazardous; in the words of Hobbes it is "solitary, poor, nasty, brutish and short." According to Hobbes, in no way is this kind of living to one's benefit and advantage. Therefore, people have to choose a person and give him/her adequate and total prerogatives to preserve security and so prevent individuals from assailing one another.

Such an approach to human beings draws Hobbes toward supreme monarchical rule, completely centralised authority (Leviathan) and the creation of powerful and commanding supervisory organisations, drags him completely away from populism and makes him conclude, thus: "It is, therefore, clear that so long as there is no government over the people to compel them to obey, they will exist in a state, which they have named 'a state of war', this war pitting individual against another" (Shumin, et al. 1999:84).

Hobbes' views on ethics, human beings and politics are highly controversial. In Hobbes' view, human beings are materialistic and pessimistic and their actions are motivated solely by self-interest. This is precisely the definition of corruption by World Bank, International Transparency, International Monetary Fund, United Nations Development Programme and many countries. It gives impetus to the creation of strong institutions to regulate human behaviour for the benefit of the majority. Thus, a state's stability

is only guaranteed by a sovereign authority, to which citizens renounce their rights. Leviathan (1651), his most celebrated work, expresses these views. Hobbes argues that for the appearance of morality in society, there is need of a centralised and resolute authority that maintains and promotes public morality. In the case of Zimbabwe, the National Integrity System comprising the executive, the legislature, the judiciary, Zimbabwe Ant-Corruption Commission (ZACC), civil society organisations, the media, Auditor-General's office, National Prosecuting Authority (NPA), political parties, Zimbabwe Republic Police (ZRP), Zimbabwe Electoral Commission (ZEC), Civil Service Commission, the Zimbabwe Human Rights Commission (ZHRC); and private sector among others are created by the government to ensure that the behaviour of Zimbabweans displays the highest degree of morality and ethical virtues. From this discussion it is clear that corruption addressed through legal reforms and enforcements targeted at the underlying causes and incentives for corruption and reducing payoffs to the individuals. Good corporate governance in both the private and public sectors are crucial. Strong governance arrangements in boards and in the running of institutions ensure that there are good checks and balances on the executive to the extent that executives can be held accountable for their actions. Weak institutions for corporate governance not only result in inefficiencies, but also encourage corrupt practices that feed into the society.

In the political realm, Hobbes is anti-democracy and a partisan of absolute monarchy. This is not a good assumption in dealing with corruption because it forbids a competitive political environment. Political accountability generally refers to the degree of responsiveness of ruling parties to the citizenry on the one hand, and to the constraints placed on the actions of public and political leaders on the other. Corrupt actions of both political and public leaders cascade down to civil society and weaken anti-corruption initiatives. Political accountability is likely to improve where there is reasonable degree of free and fair competition in the political and electoral processes. In Zimbabwe, the ruling party does everything to kill off opposition parties, and extant opposition parties, are either weak or disorganised. Further, the use of state resources for political purposes should be banned and the cost of party politics lowered through providing transparent subsidies. All these efforts should be backed by strict sanctions on parties that do not comply and declarations of assets and conduct by leaders should be strictly monitored. These proposals are anathema to Hobbes's Leviathan proposal.

Jean-Jacques Rousseau's View

Jean-Jacques Rousseau (1712-78) was a Swiss-born French writer, philosopher and political theorist. Rousseau first gained fame from his essay *Discourse on the Sciences and the Arts* (1750), an attack on the arts as a source for the increased wealth of the rich and an instrument of propaganda. In his *Discourse on Inequality* (1755), Rousseau professes the equality and goodness of 'natural man' and asserts that the golden age of humanity occurred before the formation of society, which bred competition and the corrupting influences of property, commerce, science and agriculture. The *Social Contract* (1762), influential during the French Revolution, claims that when human beings formed a social contract to live in society, they delegated authority to a government. However, they retain sovereignty and the power to withdraw that authority when necessary.

Jean-Jacques Rousseau's views are diametrically in opposition to that of Hobbes. The Universal Declaration of Human Rights, on which his famous statement has left its imprint, owes him too much. In the beginning of his celebrated book, *The Social Contract*, Rousseau writes, "Man is born free; but he lives everywhere in slavery." Article 1 of the Universal Declaration of Human Rights, thus, also states, "All human beings are born free and equal in dignity and rights."

Rousseau believes that man in the state of nature is decent, well-mannered and peace-loving and that it is the society which corrupts him. In his opinion, the debasement of man commences when he enjoins the civil society and relinquishes his own freedom. A human being left to himself/herself would never resort to attacking others and waging war against anybody:

Man is by nature amiable and timid, he runs away from least danger. He acquires a pugnacious temperament by virtue of habits and experience. Pride, interest, prejudgments, vengeance and all yearnings that can draw man to welcome the risk of death do not exist in nature. It is only when man enters human society that the thought of assaulting others enters his mind. After becoming a citizen he changes into a soldier. Therefore, man, by nature, has no inclination to wage war against his fellow human beings.

So long as man lives in the lap of nature and is not a captive of society, he/she is in harmony and intimacy with all the constituent parts of nature. His/her needs are limited and can easily be met. Neither is there any sign of avarice and covetousness, nor envy and the killing of one another. However, it is regrettable that this state of affairs does not last long. It is not clear why man abandons this comfort and serenity, and decides to establish a human society. This act is tantamount to forfeiting one's own natural freedom and destroying one's own pure nature and natural disposition, for "it is the society that corrupts and defiles beings...the more human beings gather together, to the same extent will they be further corrupted."

The source of human wars and conflicts is the desire to own, which in turn is an offshoot of society. It is this longing for possession that drives human beings to corruption. Gleaned from Rousseau's perspectives regarding the behaviour of human beings is that it is fundamentally the environment that toxifies and moulds the behaviour. For instance, a disabling political and socio-economic environment for economic growth and equitable distribution of resources promotes corruption. Thus, the following components of the environment causes corruption: wage incentives (inadequate pay, fringe benefits); sociological (custom, family pressures on government officials and ethnicity) cultural factors; leadership. It is also noteworthy that poverty, political instability and other societal forces increase public servant's susceptibility to corruption, especially when public officials feel that opportunities may vanish following defeat at polls or when their kinsmen place large demands on them. The trillion advice from Rousseau is that the environment promotes corruption, thus, any effective comprehensive anti-corruption strategy should pay attention to the human agency.

Corruption

This paper does not seek to define corruption. However, corruption is one of the most chronic macro-economic problems confronting most African countries in the twenty-first century (Zinyama, 2018). It has been considered the root cause of the various economic and political crises that have plagued the African region, and continues to aggravate not only the problem of underdevelopment of each country, but also that of abject poverty of the citizenry. Corruption takes place in the form of bribery, kickbacks, commissions, or other benefits.

Thus, corruption is in its simplest terms, the abuse of power for personal gain. Nyantakyi (2002:10) defines corruption as:

an act or a conduct of dishonesty committed by way of omission or commission which is intended to implicitly or explicitly influence, deviate from and alter the just behaviour and accepted societal propriety in order to satisfy one's selfish and/or parochial interests.

Corruption is a highly complex phenomenon. The parties involved leave very little telltale in the form of irrefutable hard evidence. Most of the corruption takes place in an informal manner and under the dark cover of isolated contacts. At times it does not even require a spoken word. Mere eye contact can establish a relationship of corruption. Societal moral virtues and ethics are eroded consequently.

Politics

Politics is the struggle for the acquisition of power. The nature of power corrupts people. A person who feels powerful rebels and forgets himself/herself, as well as his/her being a servant of God and nourishes an illusion of godhood. Power is prone to excesses and does not stop at a certain point. For instance, Hitler was ready to annihilate the whole of humanity and make himself stay in power in Germany. Thus, the evils of power should be identified and their emergence prevented. Francois Mitterrand, the former president of France who spoke about the danger of power, regards the solution to lie in controlling and guiding it, and in his words, in acquiring anti-power: “if the one who is in power...is of sound reasoning, he will search for anti-power” (Limba, 2008; Black, 2016). This anti-power prevents the excesses of power as well as the corruption of the power-holder. Anti-power within a person is called conscience. “Some of my powers only rely on my conscience” (Mitterrand cited by Limba, 2008). But one should not content himself with this anti-power; rather, “the society, likewise, ought to bring into existence anti-powers within the framework of its institutions” (Ibid.). In other words, power should be controlled through the mechanisms of distribution of power, the partnership of the people, and the supervisory bodies. Examples of anti-power mechanisms include the national integrity system as shown in Table 1 below.

Table 1. A National Integrity System

Institutional Pillar	Corresponding Core Rules/Practices
Executive	Conflict of interest rules
Legislature/Parliament	Fair elections
Public Accounts Committee of Legislature	Power to question senior officials
Auditor General	Public Reporting
Public Service	Public Service Ethics
Judiciary	Independence
Media	Access to information
Civil society	Freedom of Speech
Anti-corruption/Watchdog Agencies	Enforceable and enforced laws
Private Sector	Competition policy including procurement rules
International community	Effective Mutual legal/judicial assistance

Source: Transparency International, 2000

Nevertheless, between these two types of anti-power, it seems that the internal anti-power has primacy. Thus, the true power is the one which people exercise on their own. This is where politics and ethics are imperative. Thus, not only politics could reduce corruption, but should be, ethical. Even Machiavelli, who stresses so strongly on the independence of politics from ethics, believes that immorality is more dependent on the type of government, not on the principle of politics. Ethics and politics is the unity of the two. Lying, oppression, injustice, mischief, corruption and dishonest both in the individual and social spheres are bad.

Ethics

The pivot of ethics is truth and right while the motive of politics is interests and benefits. Ethics demands that people tell the truth even though it is against them, not to do injustice, not to take people as instruments, to be advocates of justice all the time, not to lie, to abstain from deception, not to conceal the truths. This is where politics necessitates the abandonment of some principles of ethics. Politics is nothing but arena for the expansion and preservation of power, which cannot be realised without sacrificing the principles of ethics. The problem is that if the people realise that their leaders are not behaving morally, they also wash their hands of ethics. A government which permits itself to commit injustice and deceive the people cannot expect justice and truthfulness from them. A citizen, who realises that his/her sovereign govern corrupts, fills his/her tax declaration form with lies and give wrong information. So, the government is in need of ethics. Therefore, if ethics is needed for the people, it can only be kept when the people feel that the government is also faithful and committed to the principles of ethics. Otherwise, there is no guarantee for the survival of ethics in society, and in turn, survival of the government. That is why even Machiavelli stresses on the need for the government to behave morally. Machiavelli states, “Just as good law is needed for the preservation of good morality, good morality is also necessary for the observance of law.” Thus, no government, no matter how powerful and versatile it may be, can exact obedience from the people only through police methods and by strengthening its own security system it has no alternative but to benefit from ethics and its promotion. The truth of the matter is that a moral person is the very same social and political person. Therefore, it is naïve to think that politics can be regarded as separate from ethics. In his book entitled, *Trust: the Social Virtues and the Creation of Prosperity*, the Japanese-American thinker, Francis Fukuyama (1995), points to the issue on the legitimacy crisis of the American system and regards it as caused by the negligence of the society’s leaders of the principles of ethics and their fraudulent conduct in political affairs. Deceitful conduct, moral disgrace and scandals such as Watergate provided the grounds for the mistrust of the people as regards the moral conduct of the leaders.

Synthesis of State of Nature, Politics, Ethics and Corruption

Doubtlessly, Hobbes and Rousseau’s traditions and perspectives on corruption, politics and ethics possess a part of the truth. If human beings are left to themselves and no law or moral principle controls them, certainly egoism would sway them to compete with and, finally, obliterate one another. Apparently, the cynical outlook of Hobbes is more in consonance with reality than the positive view of Rousseau. Thus, a holistic comprehensive anti-corruption strategy should not only consider laws and institutions for combating corruption but also environmental, sociological and human factors that mould and form behaviour.

THE ZIMBABWEAN SYSTEM

The Zimbabwe government has been pursuing political and economic reforms since the late 1980s in a bid to promote economic growth, reduce poverty and encourage popular participation and good governance. However, corruption assessments indicate that outcomes have been far from satisfactory (Zinyama, 2018). A 2017 study by Transparency International Zimbabwe reveals that Zimbabwe has a culture of corruption. The Global Competitiveness Report (2016-2017) identifies corruption as the third most problematic factor for doing business in Zimbabwe. The 2016 World Bank Enterprise Survey, states that 38.3% of the firms that took part in the survey identified corruption as a major constraint of doing business in Zimbabwe. A separate Global Financial Integrity report states that the country lost an estimated US\$12 billion to corruption involving smuggling and illicit financial outflows between 1980 and 2010.

The 2019 Auditor-General Report reveals that the Government of Zimbabwe overspent by more than \$2 billion without seeking parliamentary approval, while various departments and local authorities flagrantly flouted accounting procedures. According to the Zimbabwe 2018 budget, the government was supposed to spend \$4, 6 billion from the consolidated account, but ended up blowing \$7, 1 billion. At the time of writing this paper, the excess expenditure was still to be regularised in terms of Section 307 of the Constitution. The 2019 Auditor-General Report for the financial year 2018 exposed a litany of gross accounting malpractices by government departments, parastatals and local authorities that gobbled millions of dollars. The excerpts of the report are summarised in Table 1.

Table 2. 2019 Auditor-General Reports' Excerpts

The Zimbabwe Electrification Transmission and Distribution Company (ZETDC) - a unit of the Zimbabwe Electricity Supply Authority (ZESA) - has not yet taken delivery of transformers nine years after making a US\$4,9 million payment to Pito Investments. The same contractor was paid in advance an amount of US\$561 935 by the Zimbabwe Power Company (ZPC) in 2016 and has not delivered. In addition, ZPC paid R196 064 in 2016 to York International for gas that has not been received. ZETDC was previously advised by Auditor General to pursue the delivery of goods and services already paid for but did not implement the recommendations. The case mirrors the rot in most public entities as they continue haemorrhaging millions of dollars from botched deals. Grain Marketing Board (GMB) was flagged by Auditor General (AG) report for a similar deal, where an advance payment of \$1 million in 2016 for goods and services that were never delivered. Expenses worth more than \$14 million were not accounted for by Air Zimbabwe. The company failed to provide supporting documentation for operating expenses amounting to \$13 million and petty cash expenditure amounting to \$654 587. The airline had an unexplained suspense balance of \$27 million. The company has not accounted for all aircraft. The Auditor-General flagged a case involving examination management body Zimbabwe Schools Examinations Council (ZIMSEC), which continues to outsource printing services after splashing US\$3 million on its own printing press in 2016. The parastatal spent US\$2,1 million for printing the 2017 June and November examination papers. The money splurged on outsourcing the service was significantly more than the US\$1, 3 million needed to commission its own printing press. The AG report noted that the printing press was installed in 2018 after a part payment of US\$3 million, leaving a balance of US\$1,3 million. Due to the outstanding balance, the ZIMSEC could not commission the printing press. As a result, the council had to outsource the printing of Ordinary Level June and November 2017 examination papers at a cost of \$251 367 and \$1 million, respectively. National Social Security Authority (NSSA) has questionable investments made against financial advice. More than \$80 million was invested in troubled banks. NSSA invested in Treasury Bills (TBs) amounting to \$20 million with Metbank during the 2018 contrary to the Authority's risk and management recommendation. The AG report indicates malpractices at the Pig Industry Board, Civil Aviation Authority of Zimbabwe, Minerals Marketing Corporation of Zimbabwe and Zimbabwe United Passengers Company. Local authorities are similarly in the eye of a storm for lack of transparency and accountability. As at 30 May 2019, only three out of 92 local authorities had audited financial statements. For example, the Auditor-General report criticises the Harare City Council for wasting ratepayers money by hiring equipment for \$222 950 instead of repairing its own at a cost of \$159 969. The asphalt plant which mixes tar was not functional. It required \$159 969 to bring it back into service. The council in turn sought services from private companies for tar mixing and in the process incurred \$222 950. It's difficult to comprehend the economic rationale of the council's decision. Local authorities in Gweru and Mutare were rapped for the same practice. Similarly, on the welfare of citizens, the Ministry of Labour and Social Welfare did not disburse Harmonised Social Cash Transfer (HSCT) to vulnerable households to reduce household poverty, protect and enhance the livelihoods of all vulnerable children so that they refrain from risky coping strategies such as child labour and early marriages. The \$9 759 722 earmarked for HSCT programme was recalled by the Treasury on December 31, 2018 after realising that no disbursements were made, thus, depriving the beneficiaries of a better standard of living. Source: Government of Zimbabwe, (2019)

The AG report shows that there is corruption in almost all key sectors of Zimbabwe ranging from local government, public health, state entities and education among others. Governance issues, such as absence of good stewardship over public resources, have continued to dominate corruption. The systems of corruption are still largely in place. There has, however, been a variety of efforts. Among the important measures instituted to combat corruption include:

Public Finance Management Reforms

Zimbabwe has stringent statutory controls on the management and expenditure of public finances, in an effort to control public expenditure and to minimise corruption, waste and inefficiency. Such measures include independent Auditor General. The Parliament has Public Accounts Committee to exercise the oversight of executive and its budgets. The review of policies with a view to promoting transparency and accountability such as Public Entities Corporate Governance; Public Procurement and Disposal of Public Assets; Money Laundering and Proceeds of Crime; and whistleblower.

Public Finance Management (Treasury Instructions) 144 of 2019 empowers the Treasury to supervise the Consolidated Revenue Fund (CRF), charges upon CRF, appropriations from the CRF, limits of State borrowing, public debt and state guarantees, safeguards of public funds and properties, among ten (10) of the key deliverables. Furthermore, the government is no longer responsible for costs incurred when officers on official duty travel with spouses, children or dependants.

The government has enacted the Public Procurement and Disposal of Public Assets Act and came into effect on 1 January 2018. The new Act repealed the Procurement Act. The Public Procurement Act regulates the procurement cycle from procurement planning, approaches to the market, evaluation and award of tenders, contract management and disposal of assets. Specific accomplishments in modernising the public procurement system in Zimbabwe include the following:

- adoption of modern Public Procurement Regulations that define the legal, institutional, and procedural framework. The Public Procurement and Disposal of Public Assets Act came into force on 1 January 2018;
- establishment of the Procurement Regulatory Authority of Zimbabwe (PRAZ) and Board appointed in January 2018;
- development and promulgation of Procurement Regulations, Standard Bidding Documents (SBDs) and Guidelines;
- development of Training of Trainers course materials. Roll out of this training program is underway whilst a professionalization and certification module is being developed; and
- development of Electronic Government Procurement (e-GP) strategy.

Regulatory and Ease of Doing Business Reforms

The ease of doing business index ranks countries against each other based on how the regulatory environment is conducive to business operations and stronger protections of property rights. Economies with a high rank (1 to 20) have simple and friendly regulations for businesses. The 2019 Ease of Doing Business reforms are aimed at ensuring that investment promotion and economic development targets set in the Transitional Stabilisation Programme are achieved by focussing on creating a favourable climate for companies to operate in line with Vision 2030 for an upper middle-income economy. In 2015, Zimbabwe was ranked at 171 out of 189 countries and in 2016 it shifted to number 161 out of 190 countries. The

rank of Zimbabwe improved to 155 in 2018 from 159 in 2017 (Bank 2019). Currently, it takes 61 days to open a business in Zimbabwe, with all the requisite licences. The goal is 50 days.

Zimbabwe is far too bureaucratic and there are too many government agencies seeking to tax local businesses. However, Zimbabwe is commendable for setting up a fully-fledged Zimbabwe Investment and Development Agency (ZIDA) that processes investment approvals within a day. The ZIDA Act seeks to establish One Stop Investment Services centre, obliges investors to respect the country's laws and to promote good corporate social responsibility within the spheres of their operations. The Act also seeks to harmonise all investment laws in an effort to reduce bureaucracy and cut the cost of doing business in Zimbabwe and, thus, repealing the Zimbabwe Investment Authority Act, the Special Economic Zones Act and the Joint Ventures Act. The ZIDA Act also seeks to provide assurance to investors about the country's commitment to property rights, thereby, stimulating economic development in line with the goals in Vision 2030.

Anti-Corruption Structures

There was establishment of Special Anti-Corruption Unit (SACU) in 2018 housed in the Office of the President and Cabinet to improve efficiency in the fight against all forms of graft and to strengthen the effectiveness of national mechanisms for the prevention of corruption. The SACU collaborates with the Zimbabwe Anti-Corruption Commission (ZACC) and the Zimbabwe Republic Police (ZRP) and other such institutions in the fight against corruption, assists ZACC and other investigative agencies of the State in the perusal and consideration of corruption dockets, subject to the issuance of authority to Prosecute by the Prosecutor General, to prosecute corruption cases referred to the National Prosecuting Authority by investigative agencies (Maodza (2019).

In a bid to expeditiously deal with graft, the Judicial Service Commission is setting up anti-corruption courts in all the country's 10 provinces. Such courts have been opened in Bulawayo, Harare, Mutare and Masvingo. The setting up of the specialised courts is meant to complement government efforts to eliminate corruption by expeditiously dealing with corruption cases brought before the courts.

Zimbabwe Anti-Corruption Commission (ZACC) has now arresting powers. In terms of Section 2 (Paragraph h) of the definition of 'Peace Officer' under the Criminal Procedure and Evidence Act [Chapter 9:07] ZACC officers are included. In terms of the law, a police officer refers to any worker of the state, country or municipality, a sheriff or other public law enforcement agency, whose duties include arrest, searches and seizures, execution of crime or for the enforcement of law or orders. This means that in addition to ZACC officers' special powers to fight corruption, they arrest any person on reasonable suspicion of any other crimes having been committed. Before the instrument, ZACC would simply make recommendations for the police to arrest in terms of the Constitution.

Biometric Measures

The government through the Transitional Stabilisation Programme (TSP) seeks to rationalise its wage bill by ensuring an auditable and verifiable head-count. The previous Civil Service Audits undertaken by Government in 2011 and 2015, respectively, point to possible existence of ghost workers in the service, who are contributing to the burgeoning public service wage bill which accounts for over 90% of total revenues. Clearly, this goes against the thrust of re-orienting budget expenditures towards growth enhancing and poverty-reducing developmental programmes. To weed out these ghost workers, the government planned to introduce a biometric registration of all civil servants. The registration process was

designed to be rigorous and involved to capture data on Letter of Appointment, Academic and Professional Qualifications, National Identification Documents, Employment Code Numbers, and Biometric data, for instance, one's unique physical attributes such as fingerprints, DNA, iris and retina pattern, using ICT. The above system ensures that every person being paid by government for services rendered is properly accounted for.

Life Style Audits and Public Declaration of Assets

The government has not enforced its policy requiring public officials to declare their assets and disclose interests in transactions that form part of their public mandate. The efforts to strengthen the asset declaration system should be stepped up, in particular expanding the coverage of high-level officials and improving mechanisms for verification, sanctions and public access. There is need for a communication strategy. At the time of writing this paper; no one knows how far government has gone in implementing the Mandatory Declaration of Assets of 2018 by senior public officials. No one knows how effective the anti-corruption courts have been because there is no framework to at least monitor and communicate with citizens.

Nevertheless, these initiatives have in many instances not been successful. There still remains a compromising policy gap in how the government has responded to the problem of corruption. Among the major reasons for the failure of anti-corruption programmes are: lack of political will among decision makers; limited power and resources to accomplish reforms; overly ambitious and unrealistic promises; uncoordinated reforms; reforms that rely too much on law enforcement; reform strategies that target only low level officials and not the senior levels; reform strategies that do not deliver quick wins and reforms that are not fully institutionalised. Besides, for the most part, anti-corruption campaigns are often actually politically motivated struggles for power. The politicians in power accuse their predecessors or their opponents of corruption.

SOLUTIONS AND RECOMMENDATIONS

Ease of Doing Business

Public procurement should be an enabler of operations rather than an inhibitor. Policies and processes need to reduce the effort required to carry out best practice procurement. There is need for straightforward and consistent processes to enable:

- increased compliance by staff with policies;
- improved collaboration within the public; and
- reduction in transaction costs both for public sector organisations and suppliers to public entities.

At the heart of good governance lies effective public financial management, which is linked to effective public procurement, political accountability, effective checks and balances, and decentralisation and local participation. The various Auditor General's reports and media reportage attested to this assertion. Establish and operate appropriate systems of public procurement and management of public finances

based on transparency, competition and objective criteria. Public procurement is a big area of focus in preventing and fighting corruption. The importance of an ethical civil service is illustrated by the statistical correlation between merit and integrity, as demonstrated by the World Public Sector Report (2018) on human resources management.

Corruption and Public Procurement

Corruption is destroying Zimbabwe. Curbing corruption would deliver an additional more than US\$10 billion in tax revenues annually across the country, money that could support much needed investments in health, education and infrastructure. From drinking water to hospitals and death traps on roads, corruption is more omnipresent than God. It is time Zimbabwe borrows from other parts of the world like China, Thailand, Singapore and Malaysia where corruption is treated with highest contempt and sternest sanctions, including capital punishment. It does not mean that these countries are inhabited by angels, but the fact that severe sanctions are often applied has proven to be deterrent in many ways. Not all thieves would be caught but those caught would not be allowed to go with impunity. It is the regime of impunity in Zimbabwe that has made institutionalised corruption. It is not enough to continue to blame the system without looking at human agency.

Reforming Public Sector Management and Finance

Reforming public sector management is crucial in the fight against corruption, as opportunities and incentives for corruption are very much deeply rooted in public sector management. This means changing the way government does its business, that is, the internal management of public resources and the administration should be reformed. The financial management systems should provide online information for effective planning, monitoring and decision-making on a timely basis, in a reliable fashion. Without an integrated financial management system across government, it becomes difficult for the government to manage effectively and efficiently its financial resources and report on them promptly to oversight bodies.

In reforming the civil service, there should be consideration for establishing a meritocracy civil service that is well-remunerated, enhanced transparency and accountability in financial management processes, reformed sectoral service delivery, and deepened decentralisation with greater accountability. Officials are frequently appointed based on loyalty to the regime rather than merit, and are often susceptible to influence from the executive.

Ending Impunity

Effective law enforcement is essential to ensure that the corrupt are punished and break the cycle of impunity, or freedom from punishment or loss. Successful enforcement approaches need a strong legal framework; law enforcement branches; and an independent and effective judicial system. If laws were implemented many leaders, politicians, their families and cronies, business people, members of other professions, legislators, councillors, civil society leaders, police bosses, security officers, nurses, judges, priests, bishops, student leaders, college principals, civil servants, journalists and many more would be in jail. Law enforcement authorities still often hesitate to investigate the powerful. It is the reason good civil servants fear for their jobs and livelihoods when they speak out.

Citizen Empowerment

Strengthening citizens' demand for anti-corruption and empowering them to hold government accountable is a sustainable approach that helps to build mutual trust between citizens and government. For example, community monitoring initiatives have in some cases contributed to the detection of corruption, reduced leakages of funds, and improved the quantity and quality of public services. All citizens in their official dealings with public bodies, civil servants, and public officials, should be required to observe a number of responsibilities of good citizenship, in relation to, honesty, lawfulness, and the prevention of corruption. Citizens should also refrain from deceptive, dishonest or fraudulent conduct, and report any actual or suspected corruption, or misconduct to a proper authority, and refrain from making frivolous or vexatious complaints or demands.

Whistleblower Protection

The individuals who report wrongdoing at work are vital for exposing corrupt schemes and actions. Too often, however, whistleblowers face retaliation after bringing corruption, fraud and financial malpractice to light. These attacks are sometimes professional, sometimes legal, and can even be directed against the whistleblower's family, property or physical and mental well-being.

Strong Institutions: Strengthening Legislation and Rule of Law

The conventional wisdom says prevention is better than cure. Managing and being reactive to corruption through arrest is costly. It instils no public confidence in the state's ability to effectively curb corruption, especially, in a context where there is high level of impunity and seemingly selective application of the law regarding who is arrested on allegations of corruption and who is not. Corruption in the top echelons of the Zimbabwe government has weakened the state institutions that are meant to protect citizens. This becomes especially clear when one looks at the way organised crime networks can act with impunity all over the country. State institutions are failing to reign in the activities of such networks. Reporting or prosecuting these criminal activities is near impossible for officials of the judicial system. Citizens' faith in democratic institutions can only be restored by taking strong anti-corruption measures and following through on promises. Political leaders need to commit to concrete steps against corruption.

Strengthening Auditor-General (AG)

Fighting corruption requires a multi-pronged attack. It requires reforms, inter alia, in public administration, judiciary, public information, and cultural values of the society. Although there is a general agreement that the AG is effective in promoting transparency, governance and accountability, the AG still lacks adequate independence and resources to play this role.

The AG should try to create, with the help of government, an institutional mechanism to feed the results of audit in future economic planning. It means, before a development project or programme is finally approved, there should be a system of clearance from an independent body that the current project or programme plan does not commit the same mistakes which the past audit reports had pointed out. Unfortunately, this important step in the cycle of good governance is badly missing. The AG keeps on reporting same or similar irregularities or examples of mismanagement and embezzlement year after

year and the executive hardly takes note of that. Future projects and programmes commit the same mistakes. It is far more effective and economical to prevent the mistakes (intentional or unintentional) than to detect them and take corrective action.

Zimbabwe Anti-Corruption Commission (ZACC)

When the institution is established, and its powers are regulated, the most difficult task starts. The ZACC must be given sufficient resources to hire and to educate its employees, to purchase the necessary premises and technical equipment, and to pay an appropriate salary to its employees. Independence in the drafting and expenditure of its budget is also a basic pre-condition for its effective operation, as well as being a clear signal of the real intentions of the country establishing such an institution. The success of ZACC depends upon a seemingly trivial matter such as money, but money is proof of genuine political will. Even the best legal arrangements for the establishment of an ideally positioned anti-corruption institution undoubtedly fail without an appropriate budget allocation.

When an institution begins to operate it must strictly follow principles that are unconditionally linked to its work: objectivity, professionalism, impartiality, integrity, honesty, effectiveness and efficiency. If these principles are not followed, those who oppose the institution easily discredit its efforts and demand its restructuring or even its abolishment.

CONCLUSION

The study of corruption has provided evidence that despite several laws and institutions for combating corruption, there has been very little long-term success. Corruption still remains high in the Zimbabwean political agenda (Policy of Zero Tolerance for Corruption) but there is no clear strategy for combating it. Many anti-corruption institutions and integrity systems were established without much success. Despite this track record of abysmal performance, Zimbabwe is still willing to continue creating anti-corruption institutions, for several reasons: political considerations, conditionalities for donor assistance or because it is the most plausible alternative to espouse.

Until the implementation and enforcement of laws is improved, systemic corruption will remain a problem. However, corruption cannot be addressed through legal reforms and enforcements without tackling the underlying political and ethical fundamentals of the people. This, therefore, means that there needs to be a comprehensive corruption strategy based on human agency. Inevitably, the strategy requires reforms spanning from empowering civil society, reforming public sector management and finance, reforming the private sector to become more competitive, reforming the political environment to become more competitive and more transparent, controlling the powers of the executive and making it more transparent and accountable.

Although strong enforcement and monitoring are needed, they will have little long-term effect if the basic conditions that encourage corruption are not reduced. Consequently, it would appear that the objective of anti-corruption should be to undertake substantial improvement in the overall efficiency, fairness and legitimacy of the state, by addressing those underlying incentives to receive or pay bribes.

FUTURE RESEARCH DIRECTIONS

Insights and directions from this study recommend that a credible anti-corruption framework should incorporate the following:

- Comprehensive anti-corruption strategy (coordination among several watchdogs agencies, effective legal framework and law enforcement system, strong judicial system, high civil salaries; integrity, transparency and accountability in government operations, tolerant public attitude, political and administrative will; strategic plan).
- Corruption must be treated as a multisectoral issue not as a legal, police, political or economic issue, but a pervasive issue that cuts across society.
- Competitive political environment;
- Reforming and strengthening checks and balances on the executive;
- Corporate governance;
- Value orientation;
- Empowering the private sector and civil society;
- Effectively functioning regulatory framework; and
- Meritocratic systems backed with pay reforms incentives.

KEY TERMS AND DEFINITIONS

Corruption: Corruption is an act of dishonesty committed by way of omission or commission which is intended to implicitly or explicitly vary the actions and accepted societal propriety in order to gratify one's egotistical interests.

Ethics: Ethics refers to what is morally right or wrong. That is socially acceptable behaviour.

National Framework: National framework refers to the constitutional, legislative, regulatory, institutional arrangements, processes and systems that underpin the governance of an organisation.

Politics: Politics is the struggle for the acquisition of power in order to decide who gets what, how, and when.

State of Nature: 'State of Nature' is an imaginary state wherein there is no political institution and administrative organisation existing in the society and the people do their own business. Since the instinct of love and defense of one's self is very strong in everybody, the people would be at each other's throats and would destroy one another.

INTRODUCTION

e-Government has assumed a growing importance in society, enabling the modernization of public administration through the use of information and communication technologies. Several studies worldwide, particularly in United States, Europe and Gulf countries, have reported the evolution of this paradigm and proposed several frameworks for its adoption (Baker, 2009; Alhomod & Shafi, 2012; Mansour, 2012). However, technology is not the only pillar that contributes to the success of an e-Government system, and the involvement of public institutions, their employees and citizens is also crucial. The aim of e-Government is to bring public administration and public services closer to citizens in order to maximize the efficiency of public services and, therefore, contribute to a more democratic and fair society.

At European level, e-Government is seen as one of the pillars in the construction of a Europe that promotes the integration and inclusion of citizens and contributes to the creation of European citizenship. The e-Government Action Plan 2016-2020 defines three main axes in its mission (EU, 2017a): (i) to modernize public administration; (ii) to achieve the digital internet market; and (iii) to engage more with citizens and businesses to deliver high quality services. It is conceivable to conclude that e-Government is seen by European institutions as an important policy to promote citizenship, to drive change in public services, to disseminate technology, to foster the integration of systems and processes, and to promote digital inclusion of citizens.

e-Government platform should be inclusive and provide the same access opportunities to all citizens. In this sense, e-Government should be accessible. Thus, the concept of accessibility in the context of Web applications is associated with the effective availability of information to all users, regardless of the technology and platforms used and the sensory and functional capacities of the user. e-Government services should contribute to the inclusion of people with special needs and provide mechanisms to help them overcome traditional physical barriers (Leist & Smith, 2014). In fact, the European Commission (EC) argues in its program of employment, social affairs & inclusion that it is fundamental that the European Union (EU) promotes the full participation of disabled people in society (EU, 2017b). EC clearly states that “disability is a right issue and not a matter of discretion” (EU, 2017b). Additionally, it is important to consider that the European population is aging, which increases the relevance of accessibility, because it is expected that older people will face greater difficulties in using technology.

DOI: 10.4018/978-1-7998-3479-3.ch104

In this sense, we intend to identify the accessibility standards that must be adopted in the development of European and National e-Government services. We perform a comparative analysis of each of them, emphasizing their benefits for the inclusion of citizens, but also presenting their current limitations. Likewise, we intend to distinguish between the existing accessibility standards that are mandatory and the good practices that are suggested to be relevant to the inclusion of people and to promote a growing adoption of online public services by all citizens. Finally, we identify and describe how the best practices are implemented and achieved in e-Government solutions, giving some examples in Europe and in different EU countries.

The manuscript is organized as follows: Initially a literature review is performed to identify the main relevant accessibility standards adopted in European and National e-Government services. Also in this section, this study discusses the main good practices in accessibility that can be found in e-Government platforms. After that, the methodology is presented, which includes an analysis of the top-4 countries in the e-Government Benchmark 2017. Four case studies are considered: (i) Malta; (ii) Denmark; (iii) Sweden; and (iv) Estonia. Subsequently, the manuscript presents some solutions and recommendations and provides insights on future research directions. Finally, the conclusions of this study are drawn.

BACKGROUND

Web accessibility starts from the assumption that the content provided to the users should be delivered and perceptible in, at least, one of three human senses: vision, hearing or touch (Anderson, Bohman, Burmeister, & Sampson-Wild, 2004). The available means to users' interaction with Web must provide an easy and quick way to access all content available, through one or more senses, founded in four principles (Anderson et al., 2004): (i) perception; (ii) operation; (iii) understanding; (iv) robustness. Web technologies had the virtue of making accessible the information, participation and even entertainment, for people who suffer some type/degree of disability. Nevertheless, the inability to operate new ubiquitous devices, due to some type/degree of disability, still exclude people from opportunities in areas such as citizenship, work or leisure (Baptista, Martins, Gonçalves, Branco, & Rocha, 2016).

A report of World Bank (2011) estimates a thousand million people in the World suffering some type/degree of disability. More recently, Baptista et al. (2016) project towards approximately 15% of the population around the world is disabled. The perception of facts, such as: (i) the rise of the global population; (ii) the rise of disabling diseases derived from old age and the rise of live expectancy; (iii) the rise of new disabling pathological phenomena, derived from modern societies; and (iv) the recognition of new forms of disabilities reveals the impact of this population in the social, economic and political plans (Priestley et al., 2016). Socially, the awareness emerges that no one can be considered immune, to someday, suffering from an incapacitating disease or a decrease in mobility, dexterity, and cognitive ability (Money, Lines, Fernando, & Elliman, 2011). In the economic plan, the need emerges to provide goods and services to improve the life quality of the people who suffer some type/degree of disability or whose physical conditions, restricts the access to services and the ability to carry out independent living tasks, such as grocery shopping, bill payment, and accessing social services. In the political plan, the consciousness of individuals who live with people with some type/degree of disability and the disabled people themselves, put pressure on governments to adopt policies to improve his own life quality (Priestley et al., 2016). Some of the barriers of Web accessibility that justifies differences among countries meet explanation in the socio-economical differences, more particularly on aspects like, connectivity and the cost to get access to the Internet, policies to encourage the adoption of the digital or lack of inclusive Websites (Andreasson & Snarud, 2014; Kubitschke, Cullen, Dolphin, Laurin, & Cederbom, 2013).

In broad sense, Europe is progressively getting conciseness of the asymmetries, the low percentage of the countries that have government websites fully accessible and efforts are made to the approximation of the laws, regulations and administrative provisions of its member states on the accessibility of websites of public sector bodies (EU, 2012).

Accessibility Standards in European and National e-Government Services

Web accessibility can be so important as the accessibility in the urban environment, buildings or people houses. Taking into account the growth of the newest accessible means in the last years of these environments, promoted by international, national and local legislation and initiatives, a parallelism with the accessibility in the Web can be made. Governments around the world create legislation to ensure equity in the access to the Web, in order to promote inclusive participation in the so-called information society. However, the legislation is not uniform from around the World, which causes different conformity requisites from country to country and from region to region, as for example, European Internet Inclusion Initiative (EIII), in Europe, and Section 508 in the United States (Money et al., 2011; Cumbie & Kar, 2016). In the case of European Union, its member states implement Web accessibility in different forms (Andreasson & Snarud, 2014; W3C, 2017). Due to distinct conceptions and implementation stages in this area, third-parties as World Wide Web Consortium (W3C) try to fill this empty space by setting standards and promoting digital inclusion on websites (W3C, 2017). Currently, W3C lists some for the governmental policies related to web accessibility. Despite the importance of accessing this information, it does not replace to check the country legislation available for each country.

The Web Accessibility Initiative (WAI) conceptualizes three pillars which contain the guidelines, specifications and success criteria to verify the conformity of the principles of accessibility (Cooper, 2016): (i) **content** - Web Content Accessibility Guidelines (WCAG); (ii) **authoring** - Authoring Tool Accessibility Guidelines (ATAG); (iii) and **users** - User Agent Accessibility Guidelines (UAAG). In the domain of mobile technologies, the Mobile Web Initiative (MWI), has created a concept to Web development for mobile technologies, named Mobile Web Best Practices (MWBP), which main purpose is to evaluate the capability of Websites accessed from mobile devices using its own browser (Baptista et al., 2016).

These standards are in the 2.0 version and were expected new developments in order to meet (Cooper, 2016): (i) new issues on accessibility; (ii) enforce articulation between standards; (iii) put more focus on users' needs. An important contribution of the standard WCAG 2.0 was the introduction of conformity levels to reflect the accomplishment of the criteria of accessibility: (i) websites on level A, means that level A criteria are in conformity; (ii) websites on level AA, means all criteria of level A and level AA are in conformity; (iii) and websites on level AAA, means that all criteria of level A, level AA e level AAA are in conformity. This novelty facilitates the process of studying documentation for the development teams in order to create websites more accessible even if they only accomplish the first or the second levels. Nevertheless, the growth of the use of mobile and ubiquitous devices, opens challenges for new simplifications. As referred by McCathieNeville (2009), differences among WCAG and MWBP and the inherent difficulty in the establishment of a mapping between them, imply that developers need to necessarily know specifications of both.

In the future, the trend points to the accomplishment of the commitments the citizens have with the state and forces the use of the electronic government instead presidential way, bringing issues about how the public administration websites are prepared to meet citizens/users needs. Thus, it is paramount that the public administration portals can respond to the needs of the users on order so they can honor their

commitments with the government. The adoption of accessibility standards by government and public administration portals becomes a critical factor of success to the satisfaction of users' needs to ensure their obligations with the state (Velleman, Nahuis, & Van der Geest, 2017).

Good Practices in Accessibility

Our understanding of the practices in the promotion of accessibility conditions to an inclusive access to the e-Government may focus on three dimensions: (i) a deep understanding of the specific needs of the disabled people; (ii) actions of the governments and authorities focused on creating conditions to a more inclusive digital society; (iii) and the update of the standards and the monitoring and certification tools.

The way that Websites deal with the visitors does not allow a differentiation of the profile of the visitors in order to perceive their needs, limitations or capabilities, namely, in terms of accessibility. The lack of information about the behavior of the different users who suffer some type/degree of disability, does not allow a deep understanding of their specific needs to reduce barriers on the access to the Web (Baptista et al., 2016). Laboratory tests only provide closed views of a small and "controlled" population. An evaluation on how disabled users interact with government Websites in real context may lead to a more accurate perception of their difficulties, needs and expectations.

In parallel, another approach to minimize the difficulties of people with disabilities has been provided through directives from a supra state level (ONU, USA, EU) that lead member states to adopt common procedures to inspire the industry to create more accessible products. These documents do not limit creativity of industry in the field of accessibility, instead, they define the orientations that should be followed to produce better and more accessible products. An example is the European Union, which directive (EU) 2016/2102 main purpose is to promote accessibility of the websites and mobile applications of public sector bodies, in all member states (Parliament & Council, 2016). The directive was proposed by the Commission in 2012 and, after a period of negotiations and updates, was approved by the European Parliament in 2016. Member states have to transpose the most relevant provisions of the directive to their national legislation until September of 2018. The directive added on the European Accessibility Act, which aims to improve the functioning of the internal European market for accessible products and services by removing barriers created by divergent legislation.

Standards and mechanisms of evaluation of the conformity play a very important role to validate and enforce, in a technical way, legislation purposes. Despite the simplification in the WCAG standards with 2.0 version, some criticism mentions difficulties in validation of the directives. The practices carry on to evaluate accessibility of the Websites is the adoption of multiple techniques, which vary from heuristics (Hermawati & Lawson, 2016) to more complex models, in some cases, called quality models (Afonso, Angélico, Lima, & Cota, 2014). European Internet Inclusion Initiative (EIII) inspired on the directive to the accessibility of public sector bodies' websites combines existing web accessibility evaluation tools and supports user testing through crowd-sourcing (Andreasson & Snarud, 2014; Parliament & Council, 2016). According to Andreasson & Snarud (2014), it combines the benefits of automated evaluation tests with manual input and aims to be the first open source WCAG 2.0 compliant tool to provide a "mixed" test approach.

Despite the importance given to the application of good practices in the design of e-government solutions, there is no specific world ranking in this field. The current literature focuses on comparing the penetration rate of e-government services in several countries around the world on multiple perspectives such as e-participation, adherence to open data formats and cyber security policies (Obi & Iwasaki, 2015). Finally, the study conducted by Meskeel (2014), which presents a list of best e-government websites in

the world, deserves special mention. This ranking is established taking into consideration the design of the websites, highlighting as important contributions the use of responsive design, the simplicity of navigation, prominent search bars, grouping content by themes, use of icons, and the availability of multiple languages.

APPROACH AND DISCUSSION

e-Government Benchmark 2017 (EU, 2017c) realizes an assessment of e-Government services in 34 European countries, which include EU28+, as well as Iceland, Norway, Montenegro, Republic of Serbia, Switzerland, and Turkey. Four top level benchmarks indicators are established according to the e-Government Action Plan: (i) user-centric government; (ii) transparent government; (iii) cross-border mobility; and (iv) key enablers. Top-4 countries in the overall e-Government Benchmark 2017 are: (i) Malta; (ii) Denmark; (iii) Sweden; and (iv) Estonia. The analysis focused precisely on these four countries that present an overall performance in the e-Government since they appear to have potential for the identification of good practices in e-Government accessibility.

The accessibility analysis carried out followed a two phase approach. The first step consisted in the application of an automatic usability analysis tool. Several tools were considered from the Web Accessibility Evaluation Tools List¹ provided by W3C. The decision was to use the WAVE² tool, which facilitates web accessibility evaluation by providing a visual representation of accessibility issues within the page and it offers a Firefox and Chrome extension. WAVE organizes the accessibility issues in terms of errors, alerts, features, structural elements, HTML5 and Accessible Rich Internet Applications (ARIA), and contrast errors. This approach allows us to find the main accessibility issues. In a second phase perform an exploratory study through a manual inspection considering the government portal of each country. Typically, the institutional government portal is the place where citizens can obtain safely and efficiently the public services they need. Adopting this approach allow us to find good accessibility practices according to the specificities of each e-Government portal.

Malta

The first case study addresses Malta's e-Government portal³. Table 1 presents an overview about the main identified accessibility issues. Although Malta ranks 1st in the overall e-Government Benchmark 2017, we found several accessibility issues, particularly structural elements. At this level, we found is-

Table 1. Accessibility issues in Malta's e-Government portal

Category	No. of issues	Description
Errors	12	Linked image missing alternative text, missing form label, empty button and empty link.
Alerts	22	Suspicious alternative text, broken same-page link, suspicious link text, redundant title text, among others.
Features	14	Alternative text and linked image with alternative text.
Structural Elements	85	Layout table and unordered list.
HTML5 and ARIA	35	Navigation issues and ARIA tabindex.
Contrast Errors	12	Very low contrast.

sues in the construction of the tables and in the creation of lists. While tables are primarily intended for the presentation of tabular information or data, they are used in this website to control page layout and formatting, which can introduce reading and navigation order issues. Additionally, the website frequently presents an unordered bulleted list. Instead, it is recommended to use ordered lists that present a group of related parallel items.

Despite the accessibility issues, numerous important good practices are also presented. In Figure 1, we can easily identify the 1st and 2nd good practice described below at the top of the page. We highlight three good practices in this portal:

- The font size of the site can be customized by the user. Three letter sizes are set for this purpose;
- The search field allows users to search for content within the site and the domain. This is very important as often the e-Government service that users are looking for is not available on the main site;
- The form element has an action attribute set to a text value which references a server-side function.

Figure 1. Malta's e-Government portal

Denmark

The second case study considers the Danish Parliament⁴. Table 2 presents an overview of the main identified accessibility issues. Like in the previous example, most of the issues found belong to the category of structural elements. However, in this portal, besides the use of unordered lists it is also pointed out an incorrect use of level headings. Headings facilitate page navigation for users of assistive technologies. They also provide semantic and visual meaning and structure to the document. In this sense, its

Table 2. Accessibility issues in Danish Parliament portal

Category	No. of issues	Description
Errors	5	Empty links.
Alerts	6	Unlabeled form element with title and redundant links.
Features	6	Missing alternative text, null or empty alternative text and skip link target.
Structural Elements	25	Heading level issues and unordered list.
HTML5 and ARIA	9	Navigation issues and ARIA tabindex.
Contrast Errors	3	Very low contrast.

non-adoption in terms of `<h1>` and `<h2>` elements turns more difficult to identify the most relevant elements in the site. It is also worth mentioning the use of a symbol that identifies the main page functionalities, such as printing, e-mailing or dissemination of social networks (Figure 2). However, as these symbols are not standard, it may become difficult for users to access correctly and quickly the functions associated with these buttons.

The Danish Parliament site also presents some good accessibility practices. Among them we highlight two:

- Searched elements can be shown by relevance, date and title. The site displays 25, 50, 100, 200 entries per page (value that can be customized by the user);
- Menu is duplicated consistently. Therefore, the interaction with the user is simplified. Additionally, the color of the menu element changes when the user is on the object.

Figure 2. Danish Parliament portal

Sweden

The third case study considers the Government Offices of Sweden⁵. Table 3 presents an overview about the main identified accessibility issues. Features issues stand out most. 102 of 127 issues found are missing form labels. Consequently, it is recommended to present a properly associated form label to a screen reader user when the form control is accessed. Moreover, this approach allows the label to be clicked with the mouse to set focus on the form control. Additionally, we emphasize another accessibility issue on the main site. A Flash video presents some important events in which the Swedish government participated, but the video visualization presents two problems: (i) requires update of the Adobe Flash

Table 3. Accessibility issues in Government Offices of Sweden

Category	No. of issues	Description
Errors	0	
Alerts	15	Long alternative text, no-script element, missing accesskey and redundant title text.
Features	127	Missing alternative text, missing linked image with alternative text, missing form label, missing fieldset and skip link target.
Structural Elements	41	Heading levels issues, bad construction of ordered list and unordered list issues.
HTML5 and ARIA	66	Issues in header, navigation, main content and footer. Additionally, missing ARIA labels or descriptions.
Contrast Errors	6	Very low contrast.

Player; and (ii) the commands of the videos are in Swedish, although English has been defined as the language of interaction with the website.

Some good practices were also identified on the Government Offices of Sweden portal:

- The website is responsive and it can be properly navigated in desktop, cell phones and tablets devices. This situation is illustrated in Figure 3;
- In spite of the excess of information that is presented to the citizen on the main page, we register positively the non-use of pop-ups.

Figure 3. Government Offices of Sweden portal in a cell phone device

Estonia

The Estonia e-Services portal⁶ is our fourth case study. This is the aggregating portal of various e-Government services available in Estonia. Rather than having to hunt for a particular service on the Internet, Estonian citizens can simply visit this gateway site. The main found accessibility issues are presented in Table 4. The focal problems are in the use of colors that have very low contrast. This situation hinders navigation on the website. Additionally, there is an Estonian promotional video that is always loaded in the background. In addition to the struggle to visualize content, it also makes website loading a lot heavier, especially on devices with lower memory capacities. The organization of e-Government services is also another element that presents some vulnerability, since they are presented by their order of availability to the public, and it is not possible to organize them in any other way. Finally, the descriptive text associated with the features implemented by Estonia government is only discovered after the user has selected each of the topics.

Some good practices were also identified on the Estonia e-services portal:

- There is a news subscription process that is organized by various topics according to the interests of the citizens (Figure 4);
- Elements are arranged according to the intended position of their content in the reading order of the displayed content;
- The use of submenus within menus is avoided. The only exception is the “news” menu, which access is also made possible by using the keyboard.

Table 4. Accessibility issues in Estonia e-Services portal

Category	No. of issues	Description
Errors	22	Missing form label and empty link.
Alerts	12	Redundant alternative text, skipped heading level, suspicious link text, redundant link and link to PDF document.
Features	25	Missing alternative text and null or empty alternative text.
Structural Elements	40	Missing head levels, unordered list and inline frame.
HTML5 and ARIA	9	Issues in header, navigation, search and footer. Present also ARIA tabindex issues.
Contrast Errors	134	Very low contrast.

Figure 4. Estonia e-Services portal

SOLUTIONS AND RECOMMENDATIONS

Web accessibility is a relevant social, ethical and economic issue. Increasingly there is a growing need for access to information presented on e-Government platforms. It is vital that this information is accessible to all citizens, regardless of the type of disability they have. Simultaneously, it is also important to guarantee access to e-government solutions by the older population, which is increasingly necessary with the progressive aging of the population. Therefore, it clearly states that there is a need to ensure accessibility for both people with special needs and for the elderly.

A controversial subject is the implementation of e-Government solutions that can offer an attractive design and meet accessibility standards. In this sense, the dichotomy between design and accessibility emerges. Consequently, it is fundamental to reinforce the idea that both approaches are compatible. For its realization, some recommendations are suggested, such as simplicity in structuring information, concern with the semantics of navigation that can be performed with touch screens, mouse, keyboards or other devices, concern about the readability of both text and images, and testing the e-Government solutions to measure compliance with accessibility standards before the website is available to the public.

FUTURE RESEARCH DIRECTIONS

One of the main points of future research is the development of a systematic study that performs a quantitative analysis of the accessibility levels offered by the main e-Government services in the European Union. This systematic analysis should seek to identify and perform a comparative analysis of the main accessibility vulnerabilities. It is also relevant to analyze the correlation between the e-Government performance and the degree of compliance with accessibility standards.

Another research point should focus on analyzing the impact of major accessibility vulnerabilities on the public with special needs. It is intended to explore the impact of these vulnerabilities on this public, since it is expected that not all vulnerabilities found will have the same impact and importance.

CONCLUSION

Information technologies are fundamental elements in the modernization of public administration. e-Government is a key strategic process for improving democracies and promoting digital inclusion. e-Government solutions should ensure that Web accessibility standards and good practices are implemented, so that people with special needs can access public services and can be active and inclusive agents in society. In this study, it was possible to identify a set of good accessibility practices implemented in the e-Government services of the top-5 countries in the overall e-Government Benchmark 2017. It is expected that by disseminating these good practices in these reference countries in the e-Government field its adoption and dissemination may be encouraged in other countries and e-Government services.

Despite the identified good practices, which are important elements in the integration of citizens with special needs, it was possible to conclude that guaranteeing total accessibility and meeting all the rules defined in WCAG 1.0 and WCAG 2.0 standards is still a challenge. The main difficulties found were the construction of tables to define the layout of the sites, creation of unnumbered lists, incorrect use of level heading, missing alternative text in images and levels, adoption of flash technology and use of colors that present very low contrast.

The obtained results are pertinent and have significant managerial impact for Web developers and designers of e-government platforms. The found issues serve as a reference for the implementation of e-government solutions in which the same mistakes are not made and to ensure that good accessibility practices are followed. Additionally, the good practices serve as benchmarks for their large-scale adoption in emerging e-government solutions.

KEY TERMS AND DEFINITIONS

Accessible Rich Internet Applications (ARIA): Defines a way to make web content and web applications more accessible to people with disabilities.

Flash: Popular authoring software developed by Macromedia that is used to create vector graphics-based animation programs with full-screen navigation interfaces.

HTML5: Markup language used for structuring and presenting content on the world wide web.

Pop-Ups: New window that opens in the browser when visiting a web page or accessing a specific hyperlink.

Web Content Accessibility Guidelines (WCAG): Provides a wide range of recommendations for making Web content more accessible.

National Systems of Innovation Using an Application on EU Data

George M. Korres

University of Aegean, Greece

Maria P. Michailidis

University of Nicosia, Cyprus

INTRODUCTION

Innovation is a crucial part of today's economic growth and the overall advancement of society. At the same time, this accelerator contributes to the divergence in growth between the economies that can and those that cannot afford to have innovation as a corner stone of their economy. Lack of innovation can have many sources that range from a lack of the innovative spirit of society to a lack of resources (e.g. funding, equipment, human capital). Regardless of the source, it is found that often the private sector's push is not enough to close the gap between the underdeveloped and developed economies, and it is not enough to achieve innovation-related societal goals as the private sector's orientation tends to be short term and unit-focused, while societal innovation, by design, needs to be a long-term solution for the masses. As a result, public officials design schemes that aim to both, increase involvement in innovation activities and (via the first aim) close the innovation gap.

Research and Development and technical change are directly related with industrial infrastructure, productivity effects and regional development. The term of "technological policy" indicates the national technological capabilities, and also the structure and the planning on research and development. This paper attempts to examine the role of "technological policy" and the effects on sustainable development, the implications on growth and social change, in particular.

This paper focus to examine the structure and role of technological policy and also the implications on sustainable development and social change. Particularly, this paper attempts to review the theory and the current literature of the national systems of innovation. Furthermore, it attempts to apply some statistical measurement and indices in order to estimate the effects and the implications on EU innovation systems member states. For this purpose, a presentation of data and indicators has been applied. The results indicate that there are significant differences among European countries regarding national systems of innovation and policy makers should give more emphasis on the promotion of knowledge development and diffusion, R&D activities, and R&D financing (Carvalho et al, 2015).

It is well known that the adoption and diffusion of new technologies affect the structure and the competitiveness level of the economy. The choice of technology depends upon a large number of factors: the availability of technologies, the availability of information, the availability of resources, the availability of technology itself and its capacity for successful adoption to suit the particular needs and objectives. The advanced countries in technological change have tended to put more emphasis on policies to encourage the development of research and technological activities (Freeman, 1991). Usually, technological policy should aim to create a favourable "psychological climate" for the development of research and innovations (OECD, 2010a,b).

DOI: 10.4018/978-1-7998-3479-3.ch105

Countries that innovate slower will find hard to compete in the world markets where there are many successful innovators and these countries which innovate fast may also enjoy additional gains in productivity, growth, exports, even from licensing and patent fees. The government policies in new technologies and innovations aims exactly to this point: to reinforce the technological capabilities, in order to enhance the productivity, competitiveness and economic growth of their countries. The government support is usually taken under the form of “direct” and “indirect” measures, (as for instance, different grant, loans, tax concessions, and equity capital).

FOCUS OF THE ARTICLE

Most of the scenarios on national science and technological policies have been concentrated with the supply side of the science and technological system. Therefore, the governments have to examine the benefits and the cost from technological policy and related activities.

In technological and science policy economic forecasting are required, if economic gains are to be a major component of science strategy. For instance, there is little point in developing a new technology for which there is no market because of changing economic conditions. Otherwise, there is little point in developing a technology in a country when there are good reasons to believe that another technology will be developed in another country and supersede the indigenous technology, possible even before it is developed. The governments should pay more attention in the following points: First, to deal with multiple policy objectives in the establishment of priorities including their quantification. Second, to deal with uncertainty in the ex-ante assessment of cost and benefits for the proposed government-financed programmes. Third, to compare the cost-effectiveness of government intervention with other alternatives solutions. Fourth, to identify the appropriate type of government intervention. Technological policies aim to support and to promote the new technologies through different “direct and indirect measures”. The “direct measures” usually include different subsidies, or different favourable tax treatments for research and technological activities. The “indirect measures” are carried out in the pursuit of other policy objectives (i.e. competition policy, monetary, fiscal policies etc.) and consequently affected the different research and technological activities. If there is availability of data and necessary information for research and technological activities, the safer plan is to make a separate analysis for each economic sector concerning the research and technological activities and take it into account in the perspective plans. The next step is to consider and to analyse some specific sectors that can be served as a guide for further government action. The final step is to choose the method for government action (Carvalho et al, 2015).

The experience in the most of advanced countries shows that the economic growth has been close related with that of technological growth and technological planning. The history of advanced technologically countries indicates that technology transfer has been essential contributed to industrialisation and to modernisation of the whole economy in the new industrialised countries and advanced countries. However, most of the advanced technological countries import a substantial part of the technology that they use, (as for instance happened with Japan and the other European advanced technological member states).

Policies designed to alter the rate of economic growth directly tend to focus on enhancing the technological advances and the quality of labour force. The rate of technical change is affected by research expenditures and the rate of improvement of the quality of labour force is affected by investment in human capital (such as training, and education). The investment in human capital affects positively the rate of technical change.

BACKGROUND

1. The Global Environment

The experience in the most advanced countries shows that economic growth has been closely related with technological growth and technological planning. Policy research must be undertaken to determine approaches in order to reduce costs, increase access, select more effective technologies and ensure their integration, adoption and diffusion (Acs, et al. 2017).

Within this framework, the concept of innovation policy emerged as innovation policy. Nowadays, innovation policy is regarded as a part of economic policy, and its main functions are (Marzenna 2018):

- strengthening linkages in the national innovation system;
- creating favorable conditions for the implementation of new solutions (innovation);
- fostering structural changes in the industry (e.g. changes in technology, quality improvements);
- enabling companies to reap the benefits of globalization and international cooperation.

Modern innovation policy integrates some selected elements of the policy toward science and technology as well as industrial policy in order to promote development, through an effective use of new products, services and processes by enterprises, public and private organizations as well as individual people.

Innovation policy combines many different elements related to technology, education, infrastructure, etc. Innovation policy in the EU has over 20 years of history. The evolution of the innovation concept, from the linear model, which assumes that innovation is mainly a result of research and development, to a systemic model, in which innovation is the result of interactions between people, organizations and institutions caused significant adjustments in innovation strategy and policy concepts and their implementation (Marzenna 2018).

2. A Dynamic Strategy for a Coherent National Technological Policy

The concept of national systems of innovation (NSIs) emerged in the late 1980s and started to diffuse more rapidly in the early 1990s with the seminal contributions of Lundvall (1992) and Nelson (1993). It has attracted the attention of many innovation researchers and policymakers (Amable, 2000; Edquist, 2004; Freeman, 2002; Mytelka and Smith, 2002) and has rapidly achieved broad international diffusion. However, there is therefore a need for theoretically based empirical research towards varieties of NSIs, as well as determinants of innovation processes within them (Edquist, 2004, Edquist and Hommen, 2008). The analysis of system of innovations helps us understand and explain, why the development of technology is necessary in a certain direction and at a certain rate (Freeman, 1995). The government engages itself towards innovation policy because it has been considered that innovation is a key point for the national economic growth. In order to decide how the governments should decide to promote the innovations, it is useful to know the specific context in which the national government interferes (Bergek, et al., 2008).

The first approach and definition of system of innovations is that, it is a social system that is constructed by several elements, while there is a close relationship between these elements. These elements are interacting in the production, diffusion, and economic cycles. We can define the system of innovations from a narrow view. According to the narrow definition it includes organisations and institutions that of involved in searching and exploring the new technologies (such as technological institutes, and research departments). From the other side, the broad definition follows the theoretical perspective and includes

the different parts of economic structure (such as the production system, and the marketing system). On international scene, when the large countries change the orientation of research activities, this affects the small countries. Any improvement and technological sophistication in the traditional sectors for the large countries have usually pushed the small country firms for the same sectors to follow the new technologies, (Korres, 2012, Edquist, 2004).

On the other side, the advanced technological countries are usually investing in the development of new technologies in “associated strategic industries” that aim to increase the competitiveness, the economic growth and the living standards. However, in practice different countries choose different priorities for technological and economic subjects and put emphasis, in these areas in which they believe they will have more potential in future. The advanced technological countries make their plans with more long-term scientific intensive criteria and usually the priorities that choose are based in the most expensive and high technology areas, while sometimes they carry out research in collaboration with other countries. On the other side, the small countries are forced to choose these sectors, that they easily to develop, and to compete and furthermore try to strengthen the technological basis in international competitive scene (Edquist and Hommen, 2008). The existence of specialised research and technological institutions, the amounts allocated for research and technological activities and the availability of resources in the large countries, give an additional advantage and imply that the large countries are usually leading in the trends and in the fashions for the different research and technological topics. Therefore, the small countries tend to follow the “direction” set by the leading-large countries, and sometimes they are forced to follow even if the relevant research and technological topics are not the most appropriate and necessary to cover their specific needs. It is necessary, for the small countries to pay more attention to identify the specific priorities that can exploit the advantages (such as natural and human resources, and to increase their research expenditures).

Table 1 illustrates the total R&D expenditures as a percentage of GDP for European countries for the time-period 2000-2015. This indicator provided is GERD (Gross domestic expenditure on R&D) as a percentage of GDP. “Research and experimental development (R&D) comprise creative work undertaken on a systematic basis in order to increase the stock of knowledge, including knowledge of man, culture and society and the use of this stock of knowledge to devise new applications” (OECD 1981a and OECD 1981b).

Over the last ten years, R&D intensity rose in twenty-one Member States, with the highest increases in Austria (from 2.42% in 2007 to 3.16% in 2017, or +0.74 percentage points - pp) and Belgium (from 1.84% in 2007 to 2.58% in 2017, or +0.74 pp). Conversely, R&D intensity decreased in six Member States and most strongly in Finland (-0.59 pp) and Luxembourg (-0.33 pp). In Malta, R&D intensity remained at the level of 0.55%. In 2017, the Member States of the European Union (EU) spent all together almost €320 billion on Research & Development (R&D). The R&D intensity, i.e. R&D expenditure as a percentage of GDP, stood at 2.07% in 2017, compared with 2.04% in 2016. Ten years earlier (2007), R&D intensity was 1.77% (Eurostat, 2019).

With respect to other major economies, R&D intensity in the EU was much lower than in South Korea (4.22% in 2015), Japan (3.28% in 2015) and the United States (2.76% in 2015), while it was at about the same level as in China (2.06% in 2015) and much higher than in Russia (1.1% in 2015) and Turkey (0.96%). In order to provide a stimulus to the EU’s competitiveness, an increase by 2020 of the R&D intensity to 3% in the EU is one of the five headline targets of the Europe 2020 strategy. The business enterprise sector continues to be the main sector in which R&D expenditure was spent, accounting for 66% of total R&D disbursed in 2017, followed by the higher education sector (22%), the government sector (11%) and the private non-profit sector (1%). This information on Research and Development in

Source: Eurostat Database

the EU is published by Eurostat, the statistical office of the European Union. R&D is a major driver of innovation, and R&D expenditure and intensity are two of the key indicators used to monitor resources devoted to science and technology worldwide (Eurostat, 2019).

On the European Union level, the most recent completed program was the Seventh Framework Program (which was complemented with the Competitiveness and Innovation Framework Program).

Table 2. Turnover from innovation % of total turnover

	2004	2006	2008	2010	2012
EU (28 countries)	:	:	:	:	11.9
EU (27 countries)	13.7	13.4	13.3	12.8	:

Today, the Horizon 2020 is the chief innovation-stimulating program from the European Union, while the ninth framework program is being constructed (Marzenna, 2018). This picture has been reflected in the Innovation Union initiative, which was launched in 2010 as a flagship project of the Europe 2020 strategy. The Innovation Union brought a new approach to innovation policy shifting its focus from pure research to research and innovation, which address societal challenges. Innovation has been regarded as a key factor to achieve smart, sustainable and inclusive growth (European Commission, 2010).

This comparative analysis confirmed that in the period of 2010- 2017 the EU maintained its strong innovative position in the world economy and diminished the innovation gap towards the US and Japan, but was not able to reduce the distance towards South Korea. At the same time China started to catch up with innovation leaders, including the EU. Other emerging BRICS economies were not that successful in closing the innovation gap dividing them from the EU, however, some progress can be seen in the case of Russia and South Africa. These new trends need to be taken into account when setting new objectives for a future innovation strategy of the EU (Marzenna, 2018).

Table 2 illustrates the turnover from innovation as a percentage of total turnover. This indicator is defined as the ratio of turnover from products new to the enterprise and new to the market as a % of total turnover, (OECD 2010a,b). It is based on the Community innovation survey and covers at least all enterprises with 10 or more employees. An innovation is a new or significantly improved product (good or service) introduced to the market or the introduction within an enterprise of a new or significantly improved process.

This indicator is defined as the ratio of turnover from products new to the enterprise and new to the market as a % of total turnover. It is based on the Community innovation survey and covers at least all enterprises with 10 or more employees. The main conclusion that we can draw from this work and its main contribution to economic research and for companies, is that private R&D is the engine of innovation, thus, the EU should invest more in stimulating private R&D, with tax policies and other benefits, to promote investment in innovation (Carvalho et al, 2015):

- EU should continue to promote policies to support innovation in companies
- EU must innovate, finding new ways to encourage private initiative in the field of innovation seeking, thereby, to increase the number of innovative enterprises
- EU should continue and, if possible, increase public funding for innovation, as this is one of the engines of innovation.

There are a lot of proposals and strategies that can be followed and developed from the small size and weak technologically countries. Among them, an interesting view suggesting that they should develop some “new high technology areas” that may have not been developed and expertised, but the perspective potential economic benefits may be greater and they can develop a comparable advantage in the future, (Filippetti, A. & Archibugi, D., 2011). Another interesting view for the small countries suggesting the relevant strategies that are related to specialisation in some certain points for research and technological activities, in order to make an appropriate use of available resources. (Nunes et al, 2013).

Most of the scenarios on national science and technological policies have been concentrated with the supply side of the science and technological system. Therefore, the governments have to examine the benefits and the cost from technological policy and related activities. Usually, a main objective of technology policy is to increase and to enhance the use of new technologies. These technologies can be derived either from abroad or from domestic innovators and can be used domestically owned, or, in owned foreign firms. Although different countries can be choosing to develop the same kind of technologies, the policies that usually follow can differ considerably. Technological policies are based on the role of government’s intervention and are the relevant chosen priorities (such as the financial support). The divergence of national policies emergence from differences between national systems and varying views in relation to the role of the government (Edquist and Hommen, 2008). According to the different government’s policies some countries give unfair advantage to their companies in the international competition affecting the development of research activities and the new technologies. The way in

which priorities are combined and formulated in practice can vary according to the level of priority. For instance, a number of priorities that are not scientific and technological in a “strict sense” nonetheless have a considerable impact on the scale of science and technology.

SOLUTIONS AND RECOMMENDATIONS

A main objective of technology policy is to increase and to enhance the use of new technologies. These technologies can be derived either from abroad or from domestic innovators and can be used domestically owned, or, in owned foreign firms. Although different countries can be choosing to develop the same kind of technologies, the policies that usually follow can differ considerably. Technological policies are based on the role of government’s intervention and are the relevant chosen priorities (such as the financial support). The divergence of national policies emerge from differences between national systems and varying views in relation to the role of the government. According to the different government’s policies some countries give unfair advantage to their companies in the international competition affecting the development of research activities and the new technologies. The way in which priorities are combined and formulated in practice can vary according to the level of priority (Korres G. 2012, Korres G., Tsombanoglou G. 2003).

FUTURE RESEARCH DIRECTIONS

Regarding future research, it could focus on human resources, and also to examine the manner in which these resources are used. The role of universities and research institutes is an important source that can be substantial to the radical change in technological opportunities and infrastructure. The educational institutions can contribute to the introduction and diffusion of new techniques in different sectors (Korres G. 2012).

CONCLUSION

New technologies imply some direct and indirect effects or more specifically some micro effects (such as firms, and organisations) and macro effects (such as inter and intra-industrial and moreover regional effects) for the whole economy. New technologies play an important role to sectoral productivity, overall growth, employment, modernization, industrialisation, socioeconomic infrastructure and to competitiveness of a country. The principal effects for technological policy can be distinguished in demand and supply sides.

A stable macro-economic environment that encourages investment in the creation and adoption of new technologies is an important prerequisite. More important however, are the micro-economic policies that induce firms to share information, develop absorptive capacity and increase rates of adoption of new technologies, either directly (through subsidies, and financial schemes) or indirectly through alteration of the institutional and regulatory environment, (Korres G. 2012). Small countries are likely to need a more comprehensive and oriented policy of co-operative innovative effort, in order to develop their future capabilities and to make the necessary choice for technological priorities, (Korres, 2012).

The various objectives of technological policy may be subsumed under five headings:

- First, to improve the efficiency of the transfer of technology from foreign suppliers to the local users.
- Second, to increase the efficiency of operation of technology.
- Third, to strengthen the industrial base.
- Fourth, to develop the indigenous technological capability.
- Fifth, to smooth adjustment forced by new technologies.

In addition, the science and research policies should be oriented in the two main objectives:

- to assess the possibilities and needs of private and public enterprises with respect to research and technological activities.
- to choose these specific priority objectives that can describe clearly the lines of government technological action, (Korres G. 2012).

The participation of EU member states in the EU research and technological programmes can arise the opportunities for promotion and improvement of research activities, the creation of new research institutions, in order to support the innovation and the diffusion of new technologies and therefore to improve the level of economic and regional growth and social development.

KEY TERMS AND DEFINITIONS

National Innovation Systems: Is the flow of technology and information among people, enterprises and institutions which is key to the innovative process on the national level.

Research and Development (R&D): Refers to innovative activities undertaken by corporations or governments in developing new services or products, or improving existing services or products.

Technological Policy: Concerns the public means for nurturing those capabilities and optimizing their applications in the service of national goals and interests.

Comparative Analysis of Applying Behavioral Public Policy to Telecommunication Market by International Organizations

BACKGROUND

In the long history of modern society, the exercise of government regulation by the state has played an important role in the governance of its own country. Government regulation is still inevitable, such as responding to external diseconomies, dealing with disadvantages arising from an asymmetry of information and responding to moral hazards occurring in economic activities in the market.

Government regulation is authoritarian and enforcement absolute because it is regulated by the country's highest authority agency (Dye 1995). Government regulation established through such decision-making process creates a situation where law enforcement power and policy enforcement power are extremely strong. Such a policy system has allowed command and control type governance by a strict policy enforcement body of the government.

In the real society so far, government regulation by such a system has been carried out. However, recent developments in the globalization of the economy, the diversification of the values of citizens, and raising awareness of individual rights of individuals, the way of regulation centered on government regulation is shaking.

INTRODUCTION OF BEHAVIORAL PUBLIC POLICY AS A SUBSTITUTE FOR GOVERNMENTAL REGULATION

In recent years, as a new measure to compensate for the limitations of government regulations, interest in behavioral public policy has been increasing internationally. Behavior Public policy is based on the policy philosophy advocated by Thaler & Sunstein (2003). They advocate libertarian / paternalism as a concept combining contradictory social governance ideals of “libertarianism” and “paternalism.” This concept is a paternalism of relatively weak, soft, non-pushing forms and freedom of choice is not hindered; choices are not limited and do not become a heavy burden.

Thaler and Sunstein suggested that, in order to realize social governance through libertarian paternalism, “the nudge” is effective as a means of transforming people’s behavior. They argue that the nudge is every element of “the choice architecture” that predictably changes the behavior of people without forbidding people’s choices and without significantly changing economic incentives (Thaler & Sunstein 2008). It is intended that by improving the environment in which people choose, they can make wiser choices without restricting any of their options (Thaler, 2018). “The choice architecture” is an interdisciplinary

DOI: 10.4018/978-1-7998-3479-3.ch106

approach that combines and presents information to people's decision-making by providing information. In the field of cognitive psychology this information includes framing¹, anchor ring², priming³ etc., in the field of social psychology it includes inducements such as social norm⁴, bandwagon⁵ etc., and in contract theories it includes default rules⁶, opt-out schemes etc.

Oliver (2013) defines the behavioral public policy as policy measures that cause people's behavioral change to achieve the purpose of public policy. In other words, by incorporating Nudge into the public policy so far, it is possible to say that "a possible method as a way of obtaining regulatory results without setting rules, that is, a regulation other than the regulations designed to achieve the same public policy objective (Lunn 2014) "to achieve the goal of public policy.

Behavior public policy utilizing nudge is experimentally adopted in Western countries. In the UK, the Behavior Insights Team (BIT) was established in the cabinet under the direction of Prime Minister Cameron at that time, and its utilization is carried out in various policy areas. In particular, it was introduced to the policy theme, which is difficult for government intervention to individual freedom of choice, such as matters related to citizen's lifestyle and values.

In addition, in the United States, the Social and Behavioral Science Team was established in the White House, and the Presidential Decree aiming to utilize the insight of behavioral science was promulgated in September 2015. The Presidential Decree instructs us to consider whether it is possible to replace existing regulations with nudge's approach (The White House 2015).

This trend toward policy introduction of behavioral public policy is spreading to other countries as well. Such as Austria, Canada, Finland, Iceland, Ireland, New Zealand, Norway, France, Israel, Denmark and others. In addition, in the European Union which is an international organization also adapting to the public policy for member countries. Under these circumstances, the OECD is also beginning to compare practical situations to the behavioral public policy in member countries (Lunn 2014).

NECESSITY OF BEHAVIORAL POLICY TO TELECOMMUNICATION POLICY

Behavior Public policy has been mainly introduced on social welfare policies such as pension, health, medical care and public health, educational policies to raise the rate of advancement, environmental policies such as conservation of the natural environment, consumer protection policies in the market, and Telecommunication policy etc. (Lunn 2014, Thaler & Sunstein 2008, European Commission 2016, The world Bank 2015, UNCTAD 2012, The Behavioral Insights Team 2014).

As an overview of the introduction example to the telecommunication policy, in the UK, policy is taken from the viewpoint of behavioral economics in the consumer protection policy on the utilization of personal data. The initiative called "Midata" in the UK introduces regulations that force mobile communications carriers to disclose data in the event of a request for data disclosure in 2013. This regulation obliges service providers to display the main points of information in an easy-to-understand manner so that consumers can visually and easily determine their usage status (Behavioural Insights Team 2014).

Also, at the Consumer Rights Directive (CRD) of the European Union (EU), are taking consumer protection policy from the viewpoint of behavioral economics. As a case example, when buying Microsoft's operating system, it was regarded as a problem that a check button was checked in the dialog beforehand. In order to deal with this problem, CRD regulates such display. This regulation restricts such transactions that the seller side will be extremely advantageous based on the default theory that humans unconsciously choose defaults (EU 2011).

As seen in these examples, regulatory policies have been taken from the perspective of behavioral public policy in Telecommunication Market in European countries. Therefore, in this paper, will examine how behavioral public policy is adopted at international organizations which lead the public policy in international society. Furthermore, we examine the effectiveness of adopting behavioral public policy in telecommunication policy. This is because regulating the use of e-commerce and information services also touches individual values and rights. Although it is necessary to resolve policy issues, it should be avoided to take legal restrictions as much as possible. By using behavioral public policy methods, it may be possible to avoid individual values and rights restrictions.

DIRECTION OF VERIFICATION OF BEHAVIORAL PUBLIC POLICY IN TELECOMMUNICATION FIELD

Behavior Public policy leads the citizens themselves to take desirable actions as society by taking a nudge for social problems arising from people's cognitive bias without taking legal restrictive solutions (Thaler & Sunstein 2008). Because of this nature, the introduction of behavioral public policy in telecommunication policy is mainly used from the viewpoint of consumer protection.

Therefore, this paper aims to compare and verify policy stages toward introduction of behavioral public policy in consumer protection policy at each international organization. For this purpose, this study uses text analysis to examine the policy recommendations, guidelines, and reports on consumer protection policies based on behavioral insights from international organizations. Based on the analysis results, the stages at which the international agency took on consumer protection policies were classified into the following three stages:

- 1) The government recognizing the existence of consumer's cognitive bias and taking steps to remove the bias.
- 2) Verifying the social effect of the elimination of cognitive bias.
- 3) Improving the policy environment so that the government and relevant stakeholders can cooperate on the policy.

Based on this classification, aim to clarify which policy stage each international organization is leveled.

COMPARATIVE VALIDATION OF BEHAVIORAL PUBLIC POLICY IN EACH INTERNATIONAL ORGANIZATION

In this section, the main international organizations analyzed were the United Nations Conference on Trade and Development (UNCTAD), dealing with trade issues in the United Nations, the European Commission (EC), as a policy enforcement body in Europe, and the Organization for Economic Cooperation and Development (OECD), dealing with international economic issues. Specifically, publicly announced policy recommendations, guidelines, and reports of these institutions were analyzed. Based on the analysis results, the stage of the behavioral public policies in the consumer protection policy of these international organizations was compared.

Text Analysis for UNCTAD (2014) “The Benefit of Competition Policy for Consumers”

For UNCTAD, “The Benefit of Competition Policy for Consumers,” which is the UN’s consumer protection guideline (UNCTAD, 2014), was analyzed. UNCTAD points out the possibility of cognitive biases when consumers buy goods and as a guideline for UN member countries, demonstrates the need to adopt consumer protection policies based on the occurrence of cognitive bias (UNCTAD 2012, 2014).

The text analysis of this guideline revealed that 7,364 words were extracted, the number of terms type was 1,428, the average number of occurrences for the words was 3.48, and the standard deviation of the appearance frequency was 10.12. The order of the frequently appearing nouns was “consumer (208),” “competition (171),” “market (87),” “policy (76),” and “authority (51)” (see: table 1). From the numerical relationship of these frequently occurring words, it can be understood that this guideline refers to the direction of policy by the authority organization on the problem of consumer protection occurring in the course of market competition.

Table 1. Frequency of nouns in the UNCTAD report (2014)

Rank	Noun	Occurrence	Rank	Noun	Occurrence	Rank	Noun	Occurrence
1	consumer	208	8	law	28	15	benefit	21
2	competition	171	8	service	28	16	cartel	19
3	market	87	10	cost	25	16	case	19
4	policy	76	10	example	25	18	practice	18
5	authority	51	10	product	25	19	cent	17
6	price	32	13	information	24	20	choice	16
7	enforcement	30	14	benefit	21	20	decision	16

Next, in order to clarify how the elements of behavioral insight are related to this guideline, a co-occurrence network analysis was conducted. Figure 1 illustrates the co-occurrence relationship of the networks between the texts. From these co-occurrence relations, as a factor to be considered in market competition policy, consumer protection should be considered a “bias” problem that occurs in human “behavior.”

Furthermore, in order to clarify the co-occurrence relation with behavioral insight numerically, the Jaccard coefficients between each related noun and “behavioral” were calculated. The formula for calculating the Jaccard coefficient is as follows:

$$J(A, B) = |X \cap Y| / |X \cup Y|$$

The results of the analysis demonstrated that co-occurrence relationships between words related to “biases” such as “default (0.5),” “loss-aversion (0.5),” “over-optimism (0.5),” “overload (0.5),” and “time- inconsistency (0.5)” occurred in human decision-making (see Table 2).

From these results, it can be understood that consumer protection for UNCTAD (2014) is at the first stage, where the government recognizes the existence of consumer’s cognitive bias and takes steps to remove the bias.

Figure 1. Co-occurrence network of the UNCTAD report (2014)

Table 2. Jaccard coefficient between “behavioral” and each word of the UNCTAD report (2014)

No.	Word	Part of speech	Unconditional	Conditional	Jaccard
1	Asset	Noun	1 (0.015)	1 (0.500)	0.5
2	Bias	Noun	1 (0.015)	1 (0.500)	0.5
3	Concentration	Noun	1 (0.015)	1 (0.500)	0.5
4	Control	Noun	1 (0.015)	1 (0.500)	0.5
5	Default	Noun	1 (0.015)	1 (0.500)	0.5
6	Loss-aversion	Noun	1 (0.015)	1 (0.500)	0.5
7	Over-optimism	Noun	1 (0.015)	1 (0.500)	0.5
8	Overload	Noun	1 (0.015)	1 (0.500)	0.5
9	Projection	Noun	1 (0.015)	1 (0.500)	0.5
10	Time-inconsistency	Noun	1 (0.015)	1 (0.500)	0.5

Text Analysis of the EU Report “Behavioural Insights Applied to Policy”

For the EU, the recommendation of the “Behavioural Insights Applied to Policy” report is subject to analysis (Lourenco et al., 2016). In this report, practical cases of behavioral public policy in each member country were collected and disseminated. Furthermore, this report makes recommendations from the viewpoint of evidence-based policies, and in addition to traditional market surveys and social surveys, demonstrates the necessity of developing evidence-based policies by using action histories and for policymakers and researchers to use this behavior data (Lourenco et al., 2016).

A text analysis of the recommendation section, “4. Lessons learnt and recommendations,” in this report revealed that 1,023 words were extracted, the number of terms type was 401 words, the average number of occurrences was 1.72, and the standard deviation of the appearance frequency was 2.36. The

order of the frequently appearing nouns was “policy (20),” “intervention (7),” “country (5),” “initiative (5),” and “instance (5)” (See Table 3).

Table 3. Frequency of nouns in the Lourenco et al. report (2016)

Rank	Noun	Occurrences	Rank	Noun	Occurrences	Rank	Noun	Occurrences
1	policy	20	8	awareness	3	8	policy-maker	3
2	intervention	7	8	community	3	8	policy-making	3
3	country	5	8	enforcement	3	8	process	3
3	initiative	5	8	evaluation	3	8	research	3
3	instance	5	8	evidence	3	8	researcher	3
6	effectiveness	4	8	implementation	3	8	result	3
6	impact	4	8	issue	3	8	section	3

Next, in order to clarify how the elements of behavioral insight are related, a co-occurrence network analysis was conducted (see Figure 2). From this co-occurrence relation, the assertion of this document that it is important to adduce evidence to evaluate the effect of applying policy using behavioral insight was demonstrated.

Furthermore, in order to clarify the co-occurrence relationship with behavioral insight numerically, the Jaccard coefficient between each relation noun and “behavioral” was calculated. From this, the words having a relatively high Jaccard coefficient were “policy (0.46),” “initiative (0.33),” “awareness (0.22),” “section (0.22),” and “way (0.22).” Based on the results of this analysis, it can be understood that this recommendation requires the initiative and utilization of public policy using behavioral insight (see Table 4).

Figure 2. Co-occurrence network of the Lourenco et al. report (2016)

Table 4. Jaccard coefficient between “behavioral” and each word of the Lourenco et al. report (2016)

No.	Word	Part Of Speech	Unconditional	Conditional	Jaccard
1	policy	Noun	11 (0.579)	6 (0.750)	0.4615
2	BIs	Proper Noun	4 (0.211)	3 (0.375)	0.3333
3	initiative	Noun	4 (0.211)	3 (0.375)	0.3333
4	awareness	Noun	3 (0.158)	2 (0.250)	0.2222
5	section	Noun	3 (0.158)	2 (0.250)	0.2222
6	way	Noun	3 (0.158)	2 (0.250)	0.2222
7	account	Noun	1 (0.053)	1 (0.125)	0.125
8	activity	Noun	1 (0.053)	1 (0.125)	0.125
9	appetite	Noun	1 (0.053)	1 (0.125)	0.125
10	asset	Noun	1 (0.053)	1 (0.125)	0.125

From this, it can be determined that the EU Consumer protection as of 2016 is in the second stage of verifying the social effect of the elimination of cognitive bias.

Text Analysis for OECD (2016) “Consumer Protection in E-commerce OECD Recommendation”

In 2016, the OECD published the “Consumer Protection in E-commerce OECD Recommendation” as a consumer protection recommendation for e-commerce. Based on the current situation that behavioral information is utilized in e-commerce, the following recommendation was made in this report. As a general principle for consumer protection, in order to develop “transparent and effective protection,” and to protect children, vulnerable people, and disadvantaged consumers, depending on the special circumstances of e-commerce, stakeholders and governments need to gain insight from information and behavioral economics. For that reason, from the viewpoint of behavioral insight, it is necessary to obtain behavioral information, and in order to achieve the purpose of these recommendations, as the enforcement principle, governments should impose “empirical research based on insight gained from behavioral economics” in cooperation with stakeholders (OECD 2016).

A text analysis of this recommendation revealed that there were 4,732 extracted words, the number of terms type was 1,003 words, the average number of occurrences was 3.06, and the standard deviation

Table 5. Frequency of nouns in the OECD report (2016)

Rank	Noun	Occurrences	Rank	Noun	Occurrences	Rank	Noun	Occurrences
1	consumer	123	8	payment	21	14	stakeholder	14
2	business	72	9	service	20	16	resolution	13
3	e-commerce	45	10	government	18	17	authority	12
4	information	41	10	mechanism	18	18	risk	11
5	transaction	36	12	dispute	16	19	access	10
6	protection	31	12	practice	16	19	goods	10
7	recommendation	30	14	enforcement	14	19	redress	10

tion of the number of occurrences was 6.66. The order of frequently appearing nouns was “consumer (123),” “business (72),” “e-commerce (45),” “information (41),” and “transaction (36)” (See Table 5).

Next, in order to clarify how the behavioral insight elements are related in this report, a co-occurrence network analysis was conducted (See: Figure. 3). From the co-occurrence relationship illustrated in Figure 3, from the viewpoint of consumer protection, to solve technical problems in e-commerce, knowledge of behavioral economics to improve the environment in which the government and stakeholders collaborate must be utilized.

Furthermore, the Jaccard coefficient between each related noun and “behavioral” was calculated in order to clarify the co-occurrence relationship with behavioral insight quantitatively. As a result of this analysis, a strong relationship was demonstrated in nouns such as “economics (1.0),” “insight (1.0),” “evidence (0.75),” “base (0.5),” and “research (0.5).” From this result, the relationship of the nouns

Figure 3. Co-occurrence network of the OECD report (2016)

Table 4. Jaccard coefficient between “behavioral” and each word of the OECD report (2016)

No.	Word	Part Of Speech	Unconditional	Conditional	Jaccard
1	economics	Noun	4 (0.038)	4 (1.000)	1
2	insight	Noun	4 (0.038)	4 (1.000)	1
3	evidence	Noun	3 (0.029)	3 (0.750)	0.75
4	base	Noun	2 (0.019)	2 (0.500)	0.5
5	research	Noun	2 (0.019)	2 (0.500)	0.5
6	technology	Noun	3 (0.029)	2 (0.500)	0.4
7	policy	Noun	8 (0.077)	3 (0.750)	0.3333
8	addition	Noun	1 (0.010)	1 (0.250)	0.25
9	advice	Noun	1 (0.010)	1 (0.250)	0.25
10	analysis	Noun	1 (0.010)	1 (0.250)	0.25

indicating the necessity of consumer protection policy based on a user's behavioral history was demonstrated (see Table 6).

From these results, a data analysis based on the IoT environment, which analyzes the purchase/behavior history obtained from account histories, is recommended for consumer protection policies in the OECD. In addition, this is recommended for policymakers and researchers and also to urge cooperation between supplier companies utilizing the IoT.

Therefore, it can be said that the OECD's policies are in the third stage, improving the policy environment so that the government and relevant stakeholders can cooperate with the policy.

SOLUTIONS AND RECOMMENDATIONS

From these results, it can be understood that: UNCTAD (2014) consumer protection is at 1) the stage where the government recognizes the existence of the consumer's cognitive bias and takes steps to remove the bias, EU consumer protection as of 2016 is at 2) the stage of verifying the social effect of the elimination of cognitive bias, and the OECD (2016) is at 3) the stage of improving the policy environment so that the government and relevant stakeholders can cooperate with the policy (See Table 7).

Table 7. Comparison of consumer protection policies using behavioral public policy by each international organization

	1) Recognition of consumer's cognitive bias	2) Verification of the effect of behavioral public policy	3) Improvement of collaborative infrastructure with stakeholders
UNCTAD	Mentioned the necessity of developing a consumer protection policy based on the occurrence of cognitive bias.	-	-
EU	Collecting and sharing practical examples of behavioral public policy in member countries.	Verification of the social effect of the elimination of cognitive bias.	-
OECD	Understand the current situation that behavior information is utilized in e-commerce.	Developing optimal consumer protection by analyzing consumer's behavioral histories.	Cooperate with stakeholders to improve e-commerce policy based on behavioral evidence.

Based on these results, the recommendations for Japan follow. In Japan, the Ministry of the Environment launched the Behavioral Sciences Team (BEST) in 2017, and the Cabinet Office, the Ministry of Health, Labor and Welfare, the Ministry of Internal Affairs and Communications, and the Ministry of Land, Infrastructure, and Transport, among others, are cooperating with BEST and considering public policy based on behavioral insights in Japan. In 2018, BEST was at the stage of reviewing the public policy behavioral insights of European countries and the U.S. and accumulating domestic cases to demonstrate the effect of these insights in Japan.

Therefore, it can be said that Japan is transitioning from stage 1) to stage 2) of the public policy based on behavioral insights. In order to advance to the third stage 3) and improve the environment for government and stakeholders to cooperate on policy, it seems necessary to strengthen the cooperation of industry, government, and academia through BEST.

FUTURE RESEARCH DIRECTIONS

From the results of the above analysis, the stages of application of behavioral insights to the telecommunication policy in each international organization emerged clearly. In order to further evolve this research, it will be effective to structurally analyze cases of information communication policies in each country where behavioral insights are applied.

For instance, OECD's Public Governance and Territorial Development Directorate Regulatory Policy Division conducted surveys in member countries to comprehensively examine the implementation and effectiveness of public policies that applied behavioral insights in the international community. According to their report, 159 policy cases were reported using examples of telecommunication policies in countries including the U.K., Colombia, and the Netherlands (OED, 2017b).

Quantitative and qualitative analysis on the textual data of this report will help characterize and clarify various aspects of the telecommunication policy using behavioral insights. Such analysis will reveal the kinds of behavioral insights that are applied to telecommunication policy issues, why it is effective to apply behavioral insights, human habitual problems that may occur, and possible solutions to these problems by the application of behavioral insights.

In addition, the OECD has presented some forms of cognitive biases that must be taken into consideration when implementing consumer protection policies in e-commerce (OECD, 2017a) along with some suggested "de-biases" to counter the occurrence of biases (OECD, 2018). In order to develop this research, the next step mentions the effectiveness of the consumer protection policy to prevent the occurrence of cognitive bias that might arise from the characteristics of e-commerce and help consumers make appropriate choices online.

CONCLUSION

This study examined behavioral public policy as a new policy approach and alternative to how conventional government regulation is incorporated into public policy in Western countries. The U.K. and the U.S. are undertaking advanced measures in developing behavioral public policy at the national level, and following this, European countries are also actively taking measures of their own to develop public policy. Furthermore, this study confirmed that international organizations are recommending the introduction of international behavioral public policy for formulating policy and guidelines.

Based on these international policy trends, from previous literature reviews, this study clarified that behavioral public policy is a policy approach for international organizations. Furthermore, this paper conducted a comparative study of the literature survey results of the stage of the introduction of behavioral public policy at each international organization.

Using these results, previous evidence-based policies were measured by using data from social surveys and market surveys. By introducing the behavioral public policy approach, it will be possible to judge what type of nudge is effective as policy. Based on behavioral evidence, it is also possible to judge whether consumer behavior had changed in the appropriate direction or whether it was possible to protect consumers by using nudges.

In order to use this information on communication policy, cooperation between governments and relevant industries is indispensable. Thus, this study demonstrated a new policy direction based on evidence by considering the current state of international behavior public policy, and in doing so contributes to information and communication policy.

KEY TERMS AND DEFINITIONS

Behavioral Economics: Behavioral economics is economic studies that do not assume homo-economics and conduct analysis according to the reality of human psychology and emotions.

Behavioral Insights: Behavioral insights are insights gained from theories on behavioral science and social sciences such as decision theory, psychology, cognitive science, brain science, organizational behavior, and group behavior, and so on.

Behavioral Public Policy: Behavioral public policy is the development of public policy by applying behavioral insights. There are interventions aimed at transforming people's behavior into desirable behavior by using nudges and correcting cognitive bias.

Choice Architecture: Choice architecture is an interdisciplinary approach that combines and presents information on people's decision-making by providing information.

Cognitive Biases: Cognitive biases is a theory of cognitive psychology and social psychology that posits that when evaluating a certain object, an idea can be distorted in a direction according to a person's interests and hopes, and the evaluation is distorted by the features that are noticeable to the object.

Evidence-Based Policy: Evidence-based policy is a policy approach for policy planning based on numerical evidence such as statistical data and is widely adopted in various fields such as social policy, educational policy, and welfare policy.

Nudge: A nudge is a measure advocated by Thaler and Sunstein (2008) that transforms the behavior of people in an appropriate direction for society. This encourages behavioral changes using all the elements of choice architecture that do not prohibit people's choices and does not change economic incentives significantly, and so changes the behavior of people in a predictable manner.

ENDNOTES

12

- ¹ Framing: For example, when the probability of unsuccessful surgery is presented as 10%, or when the probability of successful surgery is presented as 90%, people's decisions are distorted depending on how the information is presented.
- ² Anchor ring: A human behavioral tendency that chooses close to that numerical value by presenting a certain value as an anchor.
- ³ Priming: Information given ahead of time, such as advertisements, that will affect people's decision-making and preferences.
- ⁴ Social norms: People's behaviors and decisions that are influenced by the values and expectations of the particular society or group to which they belong.
- ⁵ Band wagon: A human behavioral tendency to be influenced to make the same choice that many other people have chosen.
- ⁶ Default rules: A human behavioral tendency to select a choice by being presented with one option as the default.

A Good American President

INTRODUCTION

To what extent does the content of resumes indicate the future performance of candidates for any elected position to which they are aspiring incumbency? Using the model of business firms that may very well be “best practices,” it is suggested that voters evaluate candidates for elected office in the same manner that they might be evaluated by their employers for prospective jobs (George & Rodger, 2017).

In essence, every US citizen has an opportunity, if not an obligation, to act in the role of a hiring employer when it comes to selecting and electing candidates for public office. It cannot be presumed that every citizen in the voting public knows how to do this.

To evaluate resumes of candidates for the job of president of the US, one must have a job description and must have a list of required and desired qualifications. As it stands today, there is no job description and there is no list of qualifications beyond a skimpy set of legal requirements as specified in the US Constitution.

Voters need information to make educated decisions, and it is journalists’ job to give it to them (Andra Brichacek, 2019). Through today’s news, voters can get the basic facts on the candidates through a quick internet search, many news agencies have differentiated themselves by shifting from straight news to context and analysis as well as adopting the social media. According to Pew Research Center, about 68% of American adults get news on social media even though many have concerns about its accuracy (Matsa & Shearer, 2018). Social media gives users more direct access to candidates than ever before. Thus, the role of the third party organizations or the fourth branch of government is not only quick bringing the information to the voters, but also providing reliable information about the candidates.

The likelihood of selecting the person who has coherent skill, wide knowledge, strong experience, high proficiency, good judgement, viewing wisdom to perform in such a responsible and comprehensive capacity is the most important in this process and that can deliver a good president. Therefore, it is suggested that voters would be able to require candidates to produce certifiable evidence that they have the required qualifications and the adequate competences, because the president job surely demands it. Voters accordingly expect the outcomes based on the tasks and activities the president performs according to the skills and competences.

DOI: 10.4018/978-1-7998-3479-3.ch107

So far, voters need criteria to evaluate the candidates, thus they can judge whether he or she is a good candidate or not indeed. The authors of this chapter have researched the subject of evaluating Presidential Candidates and incumbent performance as part of an on-going series of books and papers that are concurrent with their having engaged Federal Government clients. The idea in this chapter is to connect the dots among the criteria and considerations that help citizen voters elect superior candidates to public office. While the example is the Office of President, the process applies to all elected officials.

CHAPTER OBJECTIVES

Past actions and competence are the politician's records that best predict how they might govern in the future. Uncovering these records are crucial to vet candidates and choose the best one. The purpose of this chapter is to:

1. Demonstrate how to define what makes a Presidential candidate or incumbent a good one.
2. Describe the necessity for political parties and other third-party organizations to help voters vet candidates.
3. Discuss the nature of competence and character in evaluating prospective candidates and incumbents.

BACKGROUND

This paper addresses the meaning of a “good American President,” as an instance of word-sense disambiguation (WSD). What is the meaning of “good” in this use?

Defining the Context

The authors argue that the highest order purpose of government is striving to create an ideal environment in which citizens and their commercial businesses can thrive and optimize in a global economy. In a democratic republic such as the United States, governments collaborate with private corporations to maximize the return on national resources. The aim is to develop policies that optimize return on the resources of the nation.

Governments are service-oriented enterprises that attend citizens needs as prescribed by them through levels of government systems and representation. Governments are funded by tax revenues and other fees as legislated. Legislators work with executives to establish plans, programs, services, budgets, and enabling funding (National Priorities, 2016). Central governments and even local governments are expected to balance their budget outcome and to be financially sustainable (Bolívar et, al, 2015).

Departments and Agencies comprise the Federal government as bureaucratic entities created by acts of legislation. The federal government also charters a host of corporations as independent entities. States governments also charter corporations. Most local, county, and municipal governments are public, non-profit corporations.

Ecosystem services are conditions and processes through which natural ecosystems and the species that make them up sustain and fulfil the human life. Thus provide such things like agricultural produce, timber, and aquatic organisms such as fishes and crabs (Daily, Gretchen C, 1997). Economists and ecologists have been working together for several decades to find ways to explain the dependence of humans

on the natural environment, and refine language on how ecological and economic processes interconnect for the benefit of society (Steven Cork et, al, 2007). Thus, economic “National resources” which include natural resources, raw materials, land, and capital are primary inputs to a myriad of public and private processes. There are multiple sources for determining the inventory of national resources.

Processes are all of the systems and activities that constitute the work required to produce desirable and expected outcomes. They are a product of legislation and the work of the Federal government organizations.

In the American political system, the US Constitution is the overarching control, a network of laws and regulations that guide and constrain the processes, including private sector business rules. Where processes define “how” work is done, people and technology perform the actual work (U.S. History.org, 2019) .

The government systems are staffed by people in government organizations and contractors to do the work as legislated by Congress. They are “mechanisms” that transform inputs into value-adding outcomes.

The Executive branch manages government services as a co-equal partner in the process.

The court system administers justice and resolves disputes.

Citizens and corporations staff private sector processes and systems to produce products and services offered, delivered, sold, and bought through the network of market-driven commerce. People and commercial organizations perform work, where compensation is based on individual’s value-adding contributions.

A nation’s gross domestic product is a way to quantify economic productivity. Only commercial corporations and entrepreneurs generate products and services sold in the global marketplace, which create a nation’s wealth. The Gross Domestic Product (GDP) is the current measurement method (U.S. Bureau of Economic Analysis, 2019).

Alternatively, Genuine Progress Indicator (GPI) is as a better way to measure performance with respect for economic, social, and environmental responsibility (Tejvan Pettinger, 2011). In their book *Regenerating America with Sustainable Economics*, (George & Rodger, 2017) argue that capitalism is unsustainable. Suggested is a new model needed from which to engineer sustainable economies, and the authors call it the Optimized Sustainment Model (OSM).

Outcomes

“Outcomes” include all of those associated results from government services delivery and all of those produced by private corporations and individuals.

Private Sector Outcomes

- Profit (Capital)
- Products
- Services
- Customer Satisfaction
- Assets (Intellectual property)
- Expenses (Cost of doing business)
- Physical property
- Jobs/Employment
- Debt

- Interest
- Cash flow

Government (Public Sector) Outcomes

American citizens have every right to expect the following outcomes listed in relative priority. The percentage following the result suggests as what most citizens expect.

1. Human rights as defined in the Universal Declaration of Human Rights (Hilton et.al, 2007) to which the USA is a signatory supported 100%
2. The US Constitution and The Bill of Rights guaranteed 100%
3. The Rule of Law supported 100%
4. Nation secured economically - 100%
5. Nation has a sustainable economy - 100%
6. Clean air and water - 100%
7. Nation secured militarily - 100%
8. The best education in the world - #1
9. Homeland defended from foreign and domestic terrorists - 100%
10. Employment opportunities for all who can work - 100%
11. Upward mobility for all who are prepared commensurate with ability - 100%
12. All persons provided minimal sustinment as a baseline to start - 100%
13. Social security assured for all persons - 100%
14. The freest nation in the world - #1
15. The lowest crime rate in the world - #1 in the least crime per capita

Observe that “human rights” is listed first, and that is because it is inalienable to every citizen in the world independent from the form of government or state in which they live.

In common with the Private Sector Outcomes, these are the Government's:

- Revenue from Taxes and Fees
- Products
- Services
- Customer Satisfaction
- Assets (Intellectual property)
- Expenses (Cost of service delivery)
- Physical property
- Jobs/Employment
- Debt
- Interest
- Cash flow
- Safety and Security
- Health
- Infrastructure

Let's discuss the outcomes and their relative priority. America, the state, is defined by the *US Constitution* and the *Bill of Rights*. However, those elements of the American Political System are subordinated to the larger principle of human rights for every citizen on the planet. That is why this list begins with "The Universal Declaration," and that is a teaching point for many citizens because equality for all starts with those propositions and instruments. The rule of law, the restriction of the arbitrary exercise of power by subordinating it to well-defined and established laws, is essential to all the rest.

A state must be secured economically, or else it is unviable and unable to care for citizens as they expect in a democratic republic. A country must generate sufficient tax revenue to support its obligations. It must not spend more than it can afford, as reflected in the debt and deficit.

It is essential that citizens agree with the purpose of government. The primary purpose of government is to create an environment in which individuals and their corporations can thrive in the strong economy. The aim of government is to optimize return on the nation's resources in partnership with citizens and their public and private corporations. To what extent do citizens agree with that proposition?

The rule of law applies internally and externally among trading partners and allies. Without that protection, there is no financial integrity and security.

Expectations about the economy have evolved into the concept of sustainable economics as accomplished by balancing economic, social, and environmental responsibilities. Having a sustainable economy is dependent on developing and fielding renewable energy systems. Renewable energy is a national requirement to be accomplished in public and private partnership as part of the national infrastructure.

Humanity cannot survive and thrive without clean air and water. While there is a debate about climate change and environmental science, undeniably, people have spoiled the air and water to the detriment of their health.

A nation-state must secure its integrity with military power as long as a rogue, and hostile nations exist.

Having an education system that produces superior students and citizens that compete in the global economy is essential as is providing ample employment opportunity with corresponding upward mobility.

Impoverishment must be illegal. That everyone is ensured minimal sustainment as a baseline to start.

Necessities

The readers should consider these points in a very personal manner. What do people need as a matter of necessity at various stages in their life cycles?

In the beginning:

- All citizens have affordable healthcare for their lifetime
- All citizens have affordable housing, food, and access to essential transportation
- Parents have work to perform to earn a living and to attend their obligations
- Community has police and fire protection to make the home safe
- Community has excellent schools that are accessible to young citizens
- Geniuses are provided opportunities to learn at a rate commensurate with their abilities based on their performance
- All children are encouraged to perform to their optimum ability as a matter of personal responsibility and self-reliance
- Opportunities are planned for scaling to the demographics of the emerging population

Upon high school graduation:

- HS graduates have access to college to prepare for professions and vocations
- All graduates, HS and college have access to work to earn a sustainable living
- All HS graduates have access to low interest or no interest education and training loans

Upon college and training graduation or completion:

- Graduates have access to job opportunities commensurate with their abilities
- Graduates who seek to become entrepreneurs have access to capital resources commensurate with their plans and preparation
- Graduates may expect government and private enterprise to produce sufficient upward mobility to support their advancing preparation and development

As working citizens in professions, occupations, vocations, and jobs:

- Citizens may expect the opportunity to save and invest a portion of their earnings to enhance their well-being
- Citizens may expect programs from both the private sector and government to support planned retirement
- All citizens may expect to live a good life in the absence of poverty providing that they commit to performing to the best of their ability

To what extent do citizens agree that these are necessities? Is a referendum needed?

What can citizens expect from their earnest labor and for being responsible citizens? Needed is a system that ensures exceptional reward and incentives for exceptional performance. Needed is a system that contains a balance of consequences such that poor performance is discouraged, or punished. That system needs to be shared throughout society in both private and government enterprise.

Should that system be a free-for-all or a natural accidental occurrence such as by invisible hands, or should it be more deterministic by a visible government that operates by the hands of *We the People*?

Being a responsible and self-reliant citizen who exhibits social and environmental responsibility is a sustainment position in a healthy economy.

When citizens feel responsible, they are willing to improve their country continuously. One way of development is by electing qualified candidates who meet the aspirations of citizens by implementing the good system they desire. Of course, a good president essentially contributes to develop a good system.

PRESIDENT'S JOB MODEL

To determine what makes a “good president,” one must know the job tasks for the position of President. The authors applied a job modelling technique to define the presidential tasks. The concept of modelling jobs was derived from performance management science that was developed by AT&T in the 1970s in concert with numerous consultants and academics for the purpose of engineering precise performance from the combination of people and technology. That foundation served for continuous development with the advancement of computer technology and understanding about the management of work. Accomplishing the defining of the presidential tasks required referencing the US Constitution and applying knowledge from familiarity with the US Federal Government through consulting work.

Table 1. Presidential Tasks Performance

1. Planning, staffing, organizing, and scheduling Presidential work and government functions.
1.1: Recruit and staff the cabinet and department and agency appointments.
1.2: Conduct cabinet meetings to develop and implement strategies and policies for accomplishing the nation's workload and issues.
1.3: Define the nation's outcomes and priorities for each major department and agency to produce the nation's strategic plan.
2. Develop the President's management agenda and budget and reconcile with Congress.
2.1: Assume responsibility for the legacy agenda and make adjustments to align with the President's management agenda or equivalent.
2.2: Work with cabinet heads to develop performance plans and schedules.
2.3: Work with Congressional leadership and collaborate to implement the nation's strategy, plans, and programs.
3. Initiate and approve legislation
3.1: Propose bills to Congress
3.2: Consult and advise Congress
3.3: Collaborate with industry and business leaders in the development of policies and regulations of all kinds
3.4: Approve or veto legislation
3.5: Request a declaration for war from Congress
4. Implement plans and manage on-going operations
4.1: Review and evaluate programs that include new acquisitions and on-going operations
4.2: Evaluate programs including legacy processes and engineer new ones for accomplishing required and promised outcomes
4.3: Continuously improve
5. Report progress and discuss issues with the American public to keep them informed
6. Meet with heads of state and participate in international meetings and conferences for heads of state
6.1: Participate in international economic conferences
6.2: Respond to international crises and requests for assistance
6.3: Promote democratic process and reforms

Performance analysis and modelling techniques were applied to identify the six primary tasks performed by Presidents of the United States.

The Concept of Operations (CONOPS) of the Work of the President

Generally, the CONOP is a matter of document describing the characteristics of a proposed system from the viewpoint of an individual who will use that system. A CONOP helps an organization in language what is required and what should be built for an information system. Thus it addresses the system's function, the users of the system and the system's purpose (Techopedia, 2019). The concept of operations (CONOPS) of the American Political System begins with the US Constitution that delineates the national frame of government to act on a national level.

Statement of the Goals and Objectives of the System:

The President is the Chief Executive of the Federal government enterprise and is the Commander in Chief presiding over all Departments and Agencies as well as the White House Staff.

Primary threads of responsibility include:

1. Staffing the Executive positions of all Departments and Agencies subject to Senate approval.
2. Managing Departments and Agencies to ensure the delivery of government services as prescribed by laws and regulations.
3. Planning and budgeting, establishing priorities reflected in the President's management agenda, in concert with Congress.
4. Making and changing policies, including issuing Executive Orders.
5. Strategizing, predicting, forecasting, decision making, and sense making

Managerial skills in a contemporary paradigm include the following:

- Collaborating and facilitating (aka organizing)
- Acquisition, logistics, procurement
- Financing
- Safety and security
- Strategies, tactics, policies, and constraints affecting the system
- Organizations, activities, and interactions among participants and stakeholders
- Clear statement of responsibilities and authorities delegated
- Specific operational processes for fielding the system
- Processes for initiating, developing, maintaining, and retiring the system (laws and regulations)

Candidate and Incumbent Resume and Certifications

Citizen-voters, political parties, and the media have the responsibility to vet candidates and incumbents based on their past performance and experience as aligned with the job model and statutory requirements. The process is a matter of verifying the resume and claims made, as would anyone seeking employment. For anyone wanting a job in government service, there are standards including those for Senior Executive Service, for instance. Why should citizens expect anything less for the President or any other elected official?

Therefore, the authors derived suggested skill, knowledge, and experience requirements and presented them in an evaluation matrix. Included also are considerations for a candidate's character, mental, and physical health where board-certified professionals are sought for assessment and certification. Consideration is given intelligence (IQ) in a similar manner.

Financial and legal integrity are sought just as for any federal employee requiring a security clearance. Why would not a candidate for elected office, including the President, not be subject to the same scrutiny as other government employees?

Table 3 in appendix proposes the Presidential Candidate Evaluation. The matrix contains the evaluation criteria, the value and the score of each criterion. The Qualifications Required by Law: As directed by the Constitution such as age and nationality of the President. This matrix also incorporates the President's academic qualifications, work experience, work nature, personality, knowledge with government, military background and other parameters.

Citizen-Voters make judgments based on reviewing candidate resumes as vetted and certified, and based on other information such as a President's Manifesto and alignment with Party Platforms. They produce their weighted score for comparison with other candidates under consideration.

Intelligence Quotient (IQ) is omitted from the criteria, though a board-certified declaration might be helpful. Additional research is necessary to support this topic.

DISAMBIGUATING THE MEANING OF A “GOOD AMERICAN PRESIDENT”

Issues, Controversies, Problems

Like many voters in other democratic societies, American voters are ill-prepared for their responsibility to elect officials, much less vote on issues and levies. The average American voter operates with a tenth-grade education, for instance. At no time are students instructed about how to evaluate elected officials in a manner that is consistent with the process employed by The Office of Personnel Management (OPM). As an independent agency, OPM manages the civil service of the federal government, coordinates recruiting of new government employees, and manages their health insurance and retirement benefits programs. According to the Senior Executive Policy of (Office of Personnel Management OPM, 2019), the OPM provides the day-to-day oversight and assistance to agencies as they develop, select, and manage their Federal executives. Also Members of the SES serve in the key positions just below the top Presidential appointees and they operate and oversee nearly every government activity.

“The Senior Executive Service (SES) lead America’s workforce. As the keystone of the Civil Service Reform Act of 1978, the SES was established to “...ensure that the executive management of the Government of the United States is responsive to the needs, policies, and goals of the Nation and otherwise is of the highest quality.” These leaders possess well-honed executive skills and share a broad perspective on government and a public service commitment that is grounded in the Constitution. (Office of Personnel Management OPM, 2019).

Now and never has there been a Job Application for President of the United States. That’s a glaring omission.

Issue #1: Standards are ill-defined and incomplete for evaluating elected officials including the Office of President of the United States.

Issue #2: Standards such as suggested in this chapter should result from collaboration and consensus among political parties and with implications for Constitutional amendments governing the political process.

Issue #3: Staffing the Executive branch demands timely and complete action to ensure that all Departments and Agencies have essential leadership. The process is made slow by incumbent executives being ill-prepared to staff the government and by the security Clearance process requiring time to complete.

Controversy: Addressing standards for elected office requires Congressional action and collaboration among diverse political interests. In the absent of these standards and collaboration, the economic, social and political aspects are not optimized and are not set on efficient frontier.

Problem: The American Political System is broken and divided and under attack by foreign adversaries. the chapter’s objectives in light of these issues, controversies, and problems

1. Demonstrate how to define what makes a Presidential candidate or incumbent a good one.

The “Background” covered much ground in describing what it takes to be a good president, with a significant omission. That is to consider the entire Federal Government Enterprise and its complexity. No legitimate Commander-in-Chief would approach the job as being a “know-it-all genius.” To lead the nation requires enormous humility and respect for the pluralistic democracy, the rule of law, and its co-equal partners. Divisiveness does not serve the electorate well.

Figure 1. The Government of the United States

When considering a Presidential candidate's resume, ask for evidence of where they obtained knowledge associated with the operation of each Department.

- 1.1 For every Department from which the heads are direct reports to the President, apply the Presidential Tasks.
- 1.2
- 1.3 For every Department identify and define how the organization's systems and operations serve the nation as reflected in essential outcomes.
- 1.4
- 1.5 Define the specific Presidential interactions with the US Congress regarding planning, policy-making, budgeting, implementing laws and regulations, and proposing changes.

The principal knowledge requirements include Constitutional Law and Systems Engineering because laws govern all government enterprise operations and they are implemented in an automated regulatory environment.

Knowledge, Skill, Experience, and Proficiency Requirements are derived from the President's Job Model and from a thorough consideration of all President's past performance.

The operating environment of the US Government is one of collaboration and consensus in a pluralistic structure. The government is a system of systems, governed by laws and regulations where elected officials should possess knowledge of the law and knowledge of systems engineering.

(George & Rodger, 2017) discussed the US presidential candidates and concentrated on relevance of US Constitutional Requirements and relevance of presidential candidate resumes. Education, knowledge, skill, experience, proficiency requirements as well as other qualifications can be summarized as¹

"Education

A president of the U. S. A. should be expected to have graduated, a Doctorate would be highly respected. Should it matter how well the candidate performed in school? We think so.

Curriculum Major Areas of Study

The job of President is Chief Executive of the Federal Government Enterprise that includes all of its departments and agencies. It is not reasonable for a presidential candidate to be an expert in every aspect of the federal government. It is fair to expect candidates to be 1) knowledgeable about the U. S. Constitution and three branches of government, 2) learned about management functions and disciplines, and 3) that candidates are knowledgeable about primary areas of government responsibility such as national defense and homeland security, justice, foreign policy, health, and human services, energy, and the environment for instance.

Foreign policy and public administration are separate specialized fields of study that map to presidential needs.

Skills

Managerial skills in a contemporary paradigm include the following:

- Planning
- Strategizing

- Predicting and forecasting
- Decision making
- Collaborating and facilitating (aka organizing)
- Acquisition, logistics, procurement
- Financing

Affective

“An attribute of the human experience that describes feelings or emotions and sometimes attitudes or values; often used to describe learning objectives or outcomes.

Values include:

- Allegiance to the Constitution and laws and regulations
- Loyalty to party and community
- Appreciation for diversity and collaboration
- Cherishing and relishing the opportunity for bipartisan cooperation

Work History (Sources of applying knowledge, acquiring new knowledge, and applying and developing skills and proficiency)

Military Service: In the instance of military history that is a form of public service

Community: Consideration is given to leadership and issues advocacy, for example Faith, Pays taxes, No legal encumbrance and Marital status.

Presidential Health

Voters need to make a judgment about presidential candidates' health. They can do it blindly or with the candidates' cooperation.

Presidential Character

The importance of presidential character cannot be understated, and there are professional sources for understanding the Presidential Character including the work of (Barber, James David, 1985).

“First, a president’s personality is an important shaper of his presidential behavior on nontrivial matters.

Second, presidential personality is patterned. His character, world view, and style fit together in a dynamic package understandable in psychological terms.

Third, a president’s personality interacts with the power situation he faces and the national “climate of expectations” dominant at the time he serves.

The tuning, the resonance—or lack of it—between these external factors and his personality sets in motion the dynamics of his presidency.

Fourth, the best way to predict a president's character, world view, and style is to see how they were put together in the first place. That happened in his early life, culminating in his first independent political success."

Operating Environment

Commonality

All governments have one thing in common, observes IT guru, Daniel S. Appleton, "They all redistribute wealth." No matter what the form of governance and economy, governments and their leaders make decisions on what and how the wealth of nations will be spent. They make determinations about their discretion to spend based on judgments about the elasticity of their decisions.

In the global economy, trading partners and the aggregate body of global governance determine the accuracy and truthfulness, and the viability of nation-state decisions. The aggregate body of governance can be formal organizations and arrangements of international law and agreements, or it can be informal realized through the behavior of nation states toward one another in trade and defense policies.

Optimizing the Return on National Resources

Work as described in the authors' books, suggests that the ultimate responsibility of governments is to ensure the optimal return on "national" resources. Observe that it not the same as "natural resources," though natural resources are included along with arable land, materials, capital, people, infrastructure and technology assets. What is the optimal ratio of population size and demographics to available and addressable resources? The answer lies deep in the data.

Since humanity on the small planet Earth is dependent on clean air and water, governments must ensure that the resources are protected and provided to citizens. Debate about climate change and the effect of industrialization and overpopulation on the environment all stem from the necessity to balance economic, social, and environmental responsibility in triple-bottom-line accounting.

The Chinese government must weigh the effect of industrial development on the environment just as does the US government. Hazards to local citizens and the cost of healthcare and the resulting calamities must be weighed in both the immediate and long-term.

Opportunities for invention and innovation lies in the pursuit of solutions that stem overpopulation and guide people to live and prosper in the locations and systems that afford a good life for them.

Defining a Good Life

A good life means that people are able to enjoy their needs in conditions of dignity, not living in conditions whereby the only way to satisfy their basic needs is by depriving themselves of their basic freedoms. In a good life, people are able to work in flexible way to sustain themselves and their families, providing adequate food, shelter, clothing and transportation to get to school and work. People require housing which is one of the most important requirements of a decent living and is in fact the basis of family and community stability. People want jobs that provide opportunity to improve their skill, knowledge, and proficiency to the best of their abilities. Impoverishment is unacceptable as that inhibits individuals from optimizing their contribution to society no matter what the form of government and economy.

One important economic indicator that economists consider when analyzing the nation's economic performance is the public debt. When the nation has a considerable amount of debt and when there is a revenue shortfall with mounting deficit, those are significant trouble indications. At the end of the George W. Bush presidential term in 2007, America was facing a financial collapse (James A. George, 2019).

“Financial distress is an extraordinary problem because the nation's security and viability are at stake. Nothing is more important than managing to restore financial integrity because everything else depends upon that.

What are some of the possible causes for a nation's financial stress?

- *Citizen needs exceed the government's capacity to satisfy them.*
- *Government commits to doing more than it has the revenue capacity to achieve.*
- *The nation endures disasters from which resources are insufficient to recover.*
- *The nation embarks on foreign policy that requires military support at a very high cost.”*

In America today (2019), unemployment is low and the GDP is up as is the stock market. Wages are increasing at a slow rate. However, government borrowing and spending results in enormous debt and deficits. The debt is greater than what America produces in a whole year. This high debt-to-gross domestic product ratio tells investors that the country might have problems repaying the loans (Kimberly Amadeo, 2019). How long can government sustain spending before the bubble bursts again?

Private Sector and Corporate Point of View

Corporations in free-market economies aim to optimize profits. They set aside profit to compensate executive leadership and talent, and to reserve capital for continuing improvement, innovation, and invention.

In mixed economies, corporate performance and behavior is regulated because unmitigated capitalism will maximize profits while sacrificing social and Social and natural capital even, the role of government is to create an optimal environment in which they perform while regulating for the good of the state that is their host and for the worker citizens.

The political debate in America is about how much regulation is necessary. It is about the rule of law operative in a global economy.

Looking at corporations as systems and considering their interaction with government systems is essential to corporations optimizing their performance with respect for triple-bottom-line accounting.

A GOOD AMERICAN PRESIDENT

Citizens expect a lot from their Presidents. Understandably, Americans want the President outcome which such as to taking quick action on problems facing the nation and to communicating with the public informing them resolving such problems. Good presidents have outcomes based on a strategic vision and a direction in which they want to lead the country. They are concerned doing tasks that deal with big issues and big challenges, and seek to explain their vision in a way that allows people to understand their circumstances and develop confidence in those proposals. President who succeeds makes the citizens

feel that the nation can succeed (Karl Rove, 2002)². Thus, all Americans participate in measuring the president's performance through feeling the success and achieving that success.

Measuring a Presidential Candidate or Incumbent

In order to know a Presidential candidate or incumbent is a good one; there is a need for measuring the candidate or incumbent. The challenge is to employ advanced information technology to map the ontology and to connect the threads such that information and data are actionable in evaluating and measuring presidential candidates and incumbents.

To arrive at a plausible answer, the authors created a matrix with three major columns:

1. Outcomes
2. Tasks
3. Performance Measures and Metrics

Corresponding to outcomes and tasks is another column called Performance Measures and Metrics. This approach associates "Outcomes" with "Presidential Tasks" and associated "Metrics." Some subtasks are omitted in the chart for brevity.

A President is responsible for on-going government services, systems, and operations as legislated and funded by Congress. Therefore, the first act is to manage the bureaucracy to deliver the required services to the satisfaction of Congress and Citizen Users.

Second, a President may propose changes and improvements, including retiring systems and services. However, that is subject to Congressional approval.

The question is, how does the US government measure the performance of Departments and Agencies that are responsible for services delivery? Since the President leads the Executive branch in staffing all of the departments and agencies, one of the essential tasks is staffing.

Voters Vet Candidates

As non-profit corporation political parties should be accountable and liable for vetting candidates and incumbents bearing their brand. However, the judiciary may not agree.

"Update: A federal judge on August 28. The court recognized that the DNC treated voters unfairly, but ruled that the DNC is a private corporation; therefore, voters cannot protect their rights by turning to the courts:

"To the extent Plaintiffs wish to air their general grievances with the DNC or its candidate selection process, their redress is through the ballot box, the DNC's internal workings, or their right of free speech — not through the judiciary." (Independent Voter, 2017)

Let the voters beware.

Citizens may not have the time, skill, or knowledge to properly vet candidate resumes. They are dependent on political parties, and other third-parties for assistance. Needed are technology inventions such as apps to help them manage the data and to answer question.

(The League of Women Voters, 2019) is one example of a third-party source of candidate information.

Table 2. President's Task Performance, Measures and Metrics

Outcomes	President's Task Performance	Measures & Metrics
1. Human Rights Assured	Task 2: Develop the President's management agenda and budget and reconcile with Congress Evidence of specific agenda and compliance with international agreements and commitments.	100% Universal Declaration of Human Rights
2. Constitutional/ Bill of Rights Allegiance	Task 2: Develop the President's management agenda and budget and reconcile with Congress Subtask 2.1: Assume responsibility for the legacy agenda and make adjustments to align with the President's management agenda or equivalent Subtask 2.2: Work with cabinet heads to develop performance plans and schedules Subtask 2.3: Work with Congressional leadership and collaborate to implement the nation's strategy, plans, and programs Evidence of specific agenda and compliance with international agreements and commitments. Task 3: Initiate and approve legislation Subtask 3.1: Propose bills to Congress Subtask 3.2: Consult and advise Congress Subtask 3.3: Collaborate with industry and business leaders in the development of policies and regulations of all kinds Subtask 3.4: Approve or veto legislation Subtask 3.5: Request a declaration for war from Congress Evidence of specific plans, programs, initiatives and orders resulting in specific measurable outcomes. Task 4: Implement plans and manage on-going operations Subtask 4.1: Review and evaluate programs that include new acquisitions and on-going operations Subtask 4.2: Evaluate programs including legacy processes and engineer new ones for accomplishing and producing required and promised outcomes Subtask 4.3: Continuously improve Evidence of specific plans, programs, initiatives and orders resulting in specific measurable outcomes.	100% The US Department of Justice Strategic Plan is out of date and noncompliant. The US President has allegedly obstructed justice and awaits Congressional action. The US President dishonors subpoenas from Congress by directing that they be ignored by the Executive branch.
3. Rule of Law Followed	President's actions such as Executive Orders comply with the law.	100% Measures: Court Findings for and against the President. The US Department of Justice Strategic Plan is out of date and noncompliant. Many of President Trump's EOs have been stricken by the court as being illegal and unenforceable.
4. Economic Security	Task 3: Initiate and approve legislation Subtask 3.1: Propose bills to Congress Subtask 3.2: Consult and advise Congress Subtask 3.3: Collaborate with industry and business leaders in the development of policies and regulations of all kinds Subtask 3.4: Approve or veto legislation Subtask 3.5: Request a declaration for war from Congress Task 4: Implement plans and manage on-going operations Subtask 4.1: Review and evaluate programs that include new acquisitions and on-going operations Subtask 4.2: Evaluate programs including legacy processes and engineer new ones for accomplishing and producing required and promised outcomes Subtask 4.3: Continuously improve	100% Measures and Metrics Correspond with all appropriate Departments and Agencies plans, programs, and budgets. According to Budget Request Annual Performance Plan and Reports of "The Government Performance and Results Act Modernization Act (GPRAMA) of 2010 requires Treasury and other federal agencies to formally monitor and review organizational performance through strategic reviews, the annual performance plan, and the annual performance report." "The Congressional Justification of Appropriations (CJ) reflects the President's Budget request for the Department of the Treasury and is prepared in accordance with OMB Circular A-11. The CJ includes agency priorities, requested budget levels, and performance plans and reports (in accordance with GPRAMA)."

16. Government Services Delivered	Task 1: Planning, staffing, organizing, and scheduling Presidential work and government functions Subtask 1.1: Recruit and staff the cabinet and department and agency appointments Subtask 1.2: Conduct cabinet meetings to develop and implement strategies and policies for accomplishing the nation's workload and issues Subtask 1.3: Define the nation's outcomes and priorities for each major department and agency to produce the nation's strategic plan	100% As legislated and required by law. Performance is measured by each department and agency in accordance with Congressional Oversight and Executive Branch scrutiny.

“We are all equal at the ballot box, but only if we vote. We engage millions of voters every year ensuring Americans have the information they need to participate in elections that determine our future.” Elections.

Evaluating Candidates and Incumbents

Managing the large and complex US Federal Government Enterprise requires collaboration and consensus among three co-equal branches of government. The President must possess leadership and behavioural traits for achieving results in a bipartisan environment.

Being a CEO of a private corporation is considerably different from being a US President because the aim is not profit-driven, and the relationship between the chief executive and the other branches of government is dissimilar to that of the relationship with a Board of Directors.

In some sense, Citizens are considered shareholders in the US Government because they pay for it with their taxes, and they elect leadership and representatives. Citizens receive a return on their investment as realized in services and outcomes.

Citizens expect and demand loyalty from the President to the rule of law, the US Constitution, and executing the Oath of Office with high integrity. Lying by a federal government official is against the law and therefore a President must guard their words as being honest and truthful. Contradictory is the fact that a sitting President cannot be prosecuted for crimes, and can only be impeached by Congress.

Solutions and Recommendations

The order of complexity inherent in a democratic republic and its associated Federal Government Enterprise is enormous. However, with the aid of technology and improved systems and tools, citizen voters can improve their choices and decision making.

The greatest challenge is to inspire elected officials to redouble their focus and attention to the priorities and essentials of good governance. The President is the leader in ensuring a good life for all citizens.

The specific issues and needs change in response to the global environment. America is a member of the global community from which isolation is not an option. A President must apply collaboration skills broadly in conducting foreign policy and to secure the nation and to contribute to global peace, prosperity, and security.

Political science, law, economics, and systems engineering intersect as disciplines for continuous improvement and that is what the authors wish to bring to light.

The overarching legislation governing performance management in the Federal government is The GPRA Modernization Act of 2010.

“The GPRA Modernization Act modernizes the Federal Government’s performance management framework, retaining and amplifying some aspects of the Government Performance and Results Act of 1993 (GPRA 1993) while also addressing some of its weaknesses. GPRA 1993 established strategic planning, performance planning and performance reporting as a framework for agencies to communicate progress in achieving their missions. The GPRA Modernization Act establishes some important changes to existing requirements.

The purposes of the GPRA Modernization Act are to:

- *Improve the confidence of the American people in the capability of the Federal Government, by systematically holding Federal agencies accountable for achieving program results;*
- *Improve program performance by requiring agencies to set goals, measure performance against those goals and report publicly on progress;*
- *Improve Federal program effectiveness and public accountability by promoting a focus on results, service quality and customer satisfaction;*
- *Help Federal managers improve service delivery, by requiring that they plan for meeting program goals and by providing them with information about program results and service quality;*
- *Improve congressional decision-making by providing more information on achieving statutory objectives and on the relative effectiveness and efficiency of Federal programs and spending;*
- *Improve internal management of the Federal Government; and*
- *Improve usefulness of performance and program information by modernizing public reporting”* (Bureau of Reclamation, 2010)

The question today (2019), is the Executive Branch under incumbent Donald Trump, following the law? Is Congress enforcing the law with oversight?

FUTURE RESEARCH DIRECTIONS

Because democracy and its institutions are intended to be accessible and addressable to average citizens, it is essential to develop education curricula and tools, including software applications that help voters increase their engagement and interaction in government processes. Herein lies much opportunity to break new ground with inventions and innovations.

The authors suggest establishing standards for political party platforms and for Presidential candidates for mapping their manifestos to the platforms. Also recommended is creating an “app” to assist citizen voters in evaluating candidate resumes and credentials.

CONCLUSION

This chapter raises more questions though has begun to answer many to initiate further research and actions by citizens, political parties, and the media to help ensure that the democratic republic will endure against threats to equality and freedom. Perhaps the most significant risk is from complacency and cynicism. Democracy is a living institution and is adaptive to change and improvement. It depends on intellectual investment for its survival and capacity to thrive.

ACKNOWLEDGMENT

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

KEY TERMS AND DEFINITIONS

Collaboration: Working together to create something that is better than going it alone. In a democratic republic, representatives from different political parties collaborate to attend to the needs of the nation, where getting things done in a bipartisan manner is more important than political ideology.

Concept of Operations (CONOPS): The concept of operations (CONOPS) of the American Political System begins with the US Constitution. Though there is also the notion of political parties and their role in offering ideological brands based on or relating to a system of ideas and ideals, especially concerning economic or political theory and policy. The extent to which party brands align with what the "Framers" had in mind is open for debate.

Ecosystem Services: Conditions and processes through which natural ecosystems and the species that make them up sustain and fulfil the human life. Thus, provide such things like agricultural produce, timber, and aquatic organisms such as fishes and crabs (Daily, 1997).

Group Knowledge Model: In this chapter, group knowledge model refers to the process of information about the subject to socialize the discussion and to enhance individual understanding.

Job Model: A job model is a technique for defining the work performed from a specific position in an organization. The author learned the approach while being employed by AT&T and found it compatible with process modeling techniques such as the Integrated Definition Language (IDEF) employed extensively by the US Department of Defense and other departments and agencies. Work is defined as tasks and subtasks that are akin to activities and arrayed in a logical hierarchy.

Operating Environment: In computer technology terms, an operating environment or integrated applications environment is the environment in which users run application software. In this chapter, the operating environment encompasses all of the processes and systems as legislated and funded by Congress and managed by the Executive branch under oversight from Congress. The technical infrastructure is computer and communications technology.

Optimize: To optimize in this chapter means making the highest yield and best use of government resources in the process of attending citizen needs. Optimizing requires trade-offs and deliberate consideration for risks and benefits toward producing required outcomes and associated metrics.

Optimized Sustainment Model (OSM): The authors proposed the Optimized Sustainment Model in the book *Regenerating America with Sustainable Economics* by James A. George and James A. Rodger © 2017 Archway Publishing. The idea is to develop business rules and regulations that support the application of triple-bottom-line accounting methods to measuring corporate performance. The idea is to balance rewards for economic, social, and environmental responsibility. It is a work in progress for which academics are encouraged to contribute. The model is suggested as an alternative to capitalism.

Private Sector: The part of the national economy that is not under direct government control, though for which corporations and citizens are regulated.

Public Sector: The part of an economy that is controlled by the government and funded by taxpaying citizens who control the government.

ENDNOTES

¹ These skills and others are detailed in the book.

INTRODUCTION

Tunisia is considered as an emerging economy, a very young and nascent democracy not only in Africa but also in all the Arabic Word. In fact, since the 2011 revolution, Tunisia has undergone a rapid political transformation to democracy. After six decades of autocracy, it has witnessed four consecutive free and fair elections, including the 2011 constituent assembly elections, the 2014 parliamentary and presidential elections, and the 2018 municipal elections. It approved a new constitution in 2014 that is progressive even by Western standards, enshrining not only freedom of religion but also conscience (permitting atheism) and mandating not just gender equality but an active commitment by the state to ensuring it. Tunisia has also passed progressive laws countering violence against women and racial discrimination (Grewal, 2019).

But eight years into democracy, Tunisians have become frustrated with its failure to deliver economically. The unemployment rate, which had remained at a steady 12 to 13 percent through the late 2000s, jumped to 18 percent after the 2011 revolution and remains at 15 percent today. The rate of inflation, 3 to 4 percent prior to the revolution, has doubled to 7.4 percent. Receipts from international tourism, the third-largest sector of the Tunisian economy, totaled \$3.9 billion in 2009 and have dropped to just \$1.7 billion today. By nearly all metrics, the economic situation is even worse than that which prompted the 2011 revolution (Grewal, 2019).

Accordingly, Tunisians have become increasingly disillusioned with democracy as a solution to their day-to-day problems. Nationally representative survey data from the Afrobarometer help to capture this disillusionment over the course of Tunisia’s transition. While 70 percent of Tunisians in 2013 agreed that “democracy was preferable to other forms of government,” only 46 percent agreed last year (Grewal,

DOI: 10.4018/978-1-7998-3479-3.ch108

2019). Moreover, Tunisians no longer trust their parliaments, municipal governments, and political parties. They have lost the commitment and engagement of their citizens.

In this context, what could be done to deal with this dramatic situation?

The literature review in the public management field suggests the use of digital tools as one of the multiple answers to this question. In other words, how digital tools can be used by parliaments, municipal governments, and political parties to engage citizens in the reconquest of democracy?

Desouza & Bhagwatwar (2012); Ertiö (2015); Williamson & Parolin (2013); and Zavattaro & Sementelli (2014) have claimed that we need more digital tools for actual collaboration and citizen engagement in local government activities (Falco & Kleinhans, 2018).

For Simon et al. (2017), “*the practice of democracy using digital tools and technologies*” is called “*digital democracy*”. Therefore, among these digital tools, the authors distinguish the Digital Participatory Platform (DPP) as a specific kind of collaborative social media. For Falco and Kleinhans (2018) DPPs include all the features proper to ‘conventional’ social media (such as Facebook and Twitter): they are based on Web 2.0, allowing for user-generated content, and sharing of such content. However, compared to conventional social media, DPPs also include different and more elaborate technological features.

The implementation of a Digital Participatory Platform (DPP) takes into account the mandatory use of issues and challenges that local governments face in fostering online and offline citizen engagement (Falco and Kleinhans, 2018). In fact, what any local government, especially municipality aspire or look for is not only implementing DPP, but also how this later should be designed to foster citizen engagement and democracy.

Thus, the aim of this paper is to present the implementation of a pilot digital participatory platform (DPP) called “Baladiaty” in order to foster local government-citizens collaboration and participation in Tunisia. “Baladiaty” means in the Arabic language “My municipality”. “Baladiaty” is a DPP designed, developed and commercialized by ARSELA in 2019, a Tunisian start-up located in the governorate of Sousse.

This paper will contain two main parts. The first is considered a theoretical part. The authors will focus on the two main terms and concepts of this research, namely: digital democracy, and DPP. This first part will focus on the definition of the digital participatory platform (DPP), and its role in promoting participatory democracy, citizen engagement and their ubiquitous engagement throughout the open government concept. The second part would be considered as a case study presenting a recently designed pilot DPP “Baladiaty” in Tunisia. This paper could be considered theoretical by focusing on the presentation of a pilot DPP in Tunisia, a nascent democracy.

BACKGROUND: TERMS AND CONCEPTS

In the following, the authors will focus their literature review on the main concepts of this chapter: democracy, e-democracy, and digital participatory platform (DPP). This literature review, based on recent publications, will cover the specificities of all these fundamental concepts: definitions, objectives, dimensions, forms, and models, etc.

I. Democracy

Before going further on the presentation of e-democracy and DPPs, the authors chose to focus on certain definitions of democracy, its forms, and models in order to clarify their foundation.

1. Definitions

For several researchers and patricians (Simon et al., 2017; Abu-Shanab, 2015; Dalton et al., 2007) democracy is not easy to define. Thus, before moving on the presentation of some contemporary definitions of democracy, the authors will first focus on these two antagonistic currents of thought in defining democracy: the elitists, and the participationists. In fact, among the proponents of the first current of thought called “elitists”, Lundström (2004) distinguished Schumpeter (1952), Sartori (1974), Downs (1957), and Dahl (1971) who “*recommend an elite-dominated form of democracy, on the grounds that such a system serves to promote social peace, stability, and efficiency. They regard a democratic competition between elites as more realistic and appropriate than a broad democratic participation in the exercise in political power*” (Lundström, 2004, p. 5). For instance, Schumpeter (1952, in O'Donnell, 1999) defined democracy as “... *a political method ... a certain type of institutional arrangement for arriving at political - legislative and administrative – decisions. (...) that institutional arrangement for arriving at political decisions in which individuals acquire the power to decide by means of a competitive struggle for the people's vote*” (p. 11),

Unlike the elitists, the participationists (Mill, 1983; Habermass, 1988; Pateman, 1970) “*recommend participatory democracy, on the grounds that this form of government fosters a sense for the common good, personal development, and equality. Political participation, they aver, brings good consequences*” (Lundström, 2004, p. 5). Thus, Pateman (1970 in Floridia, 2013), to define democracy, put forward the concept of “participation”. She stated, “*In the participatory theory, ‘participation’ refers to (equal) participation in the making of decisions, and political equality refers to equality of power of determining the outcome of decisions* (Pateman, 1970, p. 43)”. In fact, as stated by Floridia (2013) to explain the view of Pateman (1970) “*Equality of the power that individuals exercise in decision-making is the key of this understanding of democracy and participation*” (p. 47).

More recently, Simon et al. (2017) stated, “*democracy is a cluster of practices, structures, institutions, and movements. It's an assembly of many different elements – and it's the combination or totality of those elements that we understand to mean democracy*” (p. 11).

Abu-Shanab (2015), links “democracy” and its prosperity to the political well of the country. In fact, the greater the trust between government and citizens (by allowing citizens to participate in public policy processes and promoting open and accountable government), the greater the country's political well-being (Kneuer, 2016).

For Dalton et al. (2007), defining “democracy” implies taking into account three major alternatives: institutions and procedures, freedom and liberties, and social benefits. These constitute “the primary substantive choices in defining democracy” (p. 145).

As argued by Dalton et al. (2007), institutions and processes of representative government are considered as one of the pillars to define “democracy” and for Dahl et al. (1971 in Dalton et al., 2007) they are equated with “democracy”. Indeed, for the latter “*if citizens can participate equally in free and fair elections, and if elections direct the actions of the government, then the standards of democracy are met. Indeed, Freedom House rankings and other democracy indicators often treat free and fair elections as a defining element of democracy*” (p. 143).

The second pillar to define “democracy” is called “freedom and liberties”. For Dalton et al. (2007) they constitute the outcomes of “democracy”. In fact, its goal is to reach freedom and liberty for all citizens through democratic institutions. Moreover, when one analyzes the four core democratic values (political liberties, participation rights of citizens, equal justice before the law, and equal rights for women) listed by Diamond (1999, in Dalton et al., 2007), the notions such as rights, liberties, and freedom are ubiquitous.

The results of a survey undertaken by Bratton et al. (2005) in Africa and Latin America have found that references to liberty, freedom, and equality were the most common answers in defining the meaning of democracy. Likewise, for the results of another survey undertaken in five East European nations, Simon (1998, in Dalton et al., 2007) have found that liberty and basic rights were the first answer given by a majority of the public.

Social benefits are considered as the third pillar of democracy's definition. In nascent democracies with a social-democratic conception, social services ensure well-being and social peace (Bratton et al., 2005). In developing countries, economic benefits and a higher standard of living take precedence over social benefits. The results of McIntosh and Abele (1993 in Dalton et al., 2007) survey undertaken in East European countries, show that most people equated democracy with the economic values of prosperity, equality, and security that they considered most important to their country's democratic development. *"In contrast, the same study found that citizens in Britain, France, and West Germany emphasized the political values of political freedom, party competition, and a fair justice system"* (Dalton et al., 2007, pp.144-145).

2. Forms and Models of Democracy: Representative, Participatory (Deliberative or Collaborative), and Direct Democracy

Defining « democracy » cannot be done without introducing its forms and models. In this paper, the authors will use the terms forms and models of democracy interchangeably.

The literature review distinguishes three main models and forms of democracy: representative, participatory (deliberative or collaborative), and direct democracy. The main difference between these forms of democracy is located in the nature of the decision-making process (or the democratic process). In fact, the old conception of the democratic process is based on the inability to give the chance to all public members to interfere in the political decision-making process (Clive, 2012). This is called: "representative democracy".

Representative democracy, or representative government is a political system in which a restricted assembly is recognized as having the right to represent a people, a nation or a community. The will of the citizens is expressed through representatives who establish the laws (legislative power) and enforce them (executive power).

At present, all democratic states are representative democracies, in which laws are elaborated by representatives elected by the people or by the government, and voted by parliament. However, representative democracy can be complemented by mechanisms of "direct democracy", or basic democracy (Pohoryles, 2017), so-called because they directly give decision-making power to citizens in certain circumstances.

Direct democracy makes its role of a sovereign to the population by allowing it to take certain decisions itself, in particular by the technique of "the referendum" or that of "the popular consultation". It is based on the principle that the population as a whole will make the best decision via a popular vote, is directly concerned by the consequences of its choice: it is supposed to know, better than the elected, where its will and its interests reside (Pohoryles, 2017).

Participatory democracy can be reduced to the set of mechanisms and procedures that increase the involvement of citizens in decision-making and are based on the shortcomings of representative democracy and its limits in the involvement of citizens in decision-making, implementation, and control. For Pohoryles (2017), participatory democracy limits the extent of public participation and quite often leads to decisions that are not legally binding for the government or parliament.

Simon et al. (2017), distinguished between deliberative democracy and collaborative democracy as two forms of participatory democracy. The main idea of deliberative democracy, inspired by the theories of John Rawls and Jürgen Habermas, is that a political decision is truly legitimate when it proceeds from the public deliberation of equal citizens. In relation to participatory democracy, it emphasizes the need for well-argued debates among citizens. The collaborative democracy is defined as a political system where each citizen can propose his ideas without an intermediary, that is to say without delegation of power to specialists, experts or political representatives, to participate directly in the elaboration of a common political project and involve in decisions.

These two forms of participatory democracy could be considered as the foundations of modern democracy called e-democracy or digital democracy.

II. E-democracy

In this section, the authors will introduce “e-democracy” by defining it, enumerate its typology, and conclude with its dimensions.

1. Definitions

The literature review related to political sciences is very rich in terms of definitions of e-democracy, also called digital democracy. However, some researchers agreed that there is no common definition of e-democracy (Kneuer, 2016; Simon et al., 2017).

Simon et al. (2017) defined e-democracy as *“the practice of democracy using digital tools and technologies”*. But at the same time, they distinguished between “minimalist” and “maximalist” definitions of digital democracy. In fact, *“the former focuses on giving citizens access to governmental information and enabling them to interact with government through, for example, online consultations and transactional services online. The latter envisages a more participatory role for citizens, enabling them to collaborate with government officials as well as make their own decisions about how they and their local communities are governed”*. (Tuzzi et al., 2007 in Simon et al., 2017, p. 11).

For Kneuer (2016) digital democracy is *“an overarching concept, namely the use of ICT by political actors (government, elected officials, media, political/societal organizations, and citizens) within political and governance processes in today’s representative democracy”* (p. 669). For some other authors, e-democracy is equated with citizen participation (Manoharan and Holzer, 2012, in Kneuer, 2016).

Kies et al. (2004, in Abu-Shanab, 2015) defined “e-democracy” as *“the use of ICT tools to empower citizens and enable them to put politicians accountable for their actions, and to facilitate the interaction between citizens and their representatives to make the political process more effective”* (p. 19). Hence, this definition corresponds to the “maximalist” definition of Simon et al. (2017).

As to van Dijk (2013), the definition of digital democracy is linked to the use of digital media. He argued that digital democracy could be defined as *“the pursuit and the practice of democracy in whatever view using digital media in online and offline political communication”* (p. 4). He adds that *“the online-offline distinction should be added because political activities are not only happening on the Internet but also in physical meetings where mobile digital media are used for assistance”*. (p. 4)

Tsagarousianou (1999, in van Dijk, 2013), distinguished three claims in favor of digital democracy:

1. Digital democracy improves *political information retrieval and exchange* between governments, public administrations, representatives, political and community organizations and individual citizens.
2. Digital democracy supports *public debate, deliberation and community formation*.
3. Digital democracy enhances *participation in political decision-making* by citizens.

2. Typology for Digital Democracy

Simon et al. (2017) developed a typology to identify different aspects of digital democracy (see Figure 1). They state that it is grounded in practice so that it would be useful for practitioners, policymakers, and citizens in order to explain “*how democratic institutions can make use of digital technologies and how citizens themselves can be involved in the practice of everyday democracy – such as raising specific concerns, developing and scrutinizing legislative proposals, making decisions or holding public officials to account. The typology we set out below aims to set out these ‘everyday’ activities*” (p. 12).

Figure 1. A typology of digital democracy (Simon et al., 2017)

3. E-democracy and its Dimensions

Kneuer (2016) argued that e-democracy is a three-dimensional concept. It encompasses free and equal access to the Internet, e-participation, and e-government. These concepts are designed as a “concept tree” in the sense of Kneuer (2016). In what follows, the authors will define and present each of these concepts.

The first dimension called “free and equal access” which is also composed of two sub-dimensions: legal provision and technical infrastructure. These are considered as the basic conditions to allow e-

democracy. The former condition (legal provision) is considered as the ability of a country to guarantee Internet freedom use and content regulation for its citizens, public and private organizations. The latter is correlated to the former. In fact, the technical infrastructure is considered as a “*sine qua non*” condition to guarantee Internet freedom without “*any filtering or blocking by independent offices or regulatory bodies*” (Kneuer, 2016, p. 671).

van Dijk (2010, in van Dijk, 2013) states that the second dimension of e-democracy called “e-Participation” can be defined as “*the use of digital media to mediate and transform the relations of citizens to governments and to public administrations in the direction of more participation by citizens*” (p. 9). Likewise, he argued that e-participation is related and correlated to the concept of “the policy process” through its five phases, namely: agenda setting, policy preparation, decision making, policy execution, and policy evaluation.

The detractors of this new political approach consider that citizens can not intervene in all these five phases. The only ones are agenda setting, policy preparation, and policy evaluation. Applying e-Participation in decision making and policy execution is contested. In fact, decision-making, and policy execution are currently reserved for political representatives and public administrations executing the decisions of governments and parliaments. In the context of representative democracy, the only possibilities to intervene are e-voting and e-campaigning.

For Kneuer (2016), “e-participation” is considered as the second e-democracy dimension which is characterized by three basic elements. The first is based on the fact that e-Democracy necessitates a “*two-way channel communication*”:

- “a top-down direction – or in the words of Coleman and Blumler: e-democracy from above –
- and a bottom-up direction – or democracy from below (Coleman and Blumler, 2009: 90–139; see also OECD, 2003: 30)” (Kneuer, 2016, p. 671).

These two-way channel communications are considered by Kneuer (2016) as the two dimensions in e-participation.

The second element is “the decision-making process”. For Kneuer (2016), it is necessary to distinguish between “e-voting” and “engagement” in the decision-making process. In fact, there is a fundamental difference between these two notions which is based on the role given to the “citizen” in the political decision-making process.

In modern democracies one could distinguish between formal and informal ways to participate in decisions: “*Formal participatory modes are directed to the government, or the parliament; informal ones have no direct addressee, but should put pressure on the decision-takers through their broad public support of a specific claim. In the first case, they can be initiated both by a Citizens’ Initiative or by the government or parliament, and they can define specific groups that are entitled to participate, mostly relating to the group that is affected by the issue at hand. Examples of this are, decisions about an urban, or a regional issue, or decisions that concern specific interest groups, like trade unions, or Chambers of Commerce*” (Pohoryles, 2017, p. 9).

Pohoryles (2017) argued that the voting system is the only participative element in a classical form of democracy. He added that “... *the notion of “Stimme abgeben” (in English: to cast a vote), which literally means to delegate decisions to people, or parties and to refrain from any further influence on specific policies*” (p. 8).

Electronic voting or e-voting is defined as a “*type of vote which is done through electronic systems. (...) Electronic voting, also known as e-voting, implies the use of technology ... It is a form of eGov-*

ernance, but as eDemocracy as well. (...) With respect to eDemocracy one can expect, for instance, a higher participation rate and inclusion of the otherwise challenged - for being away from their domicile or for being physically impaired” (Pohoryles, 2017, p. 9).

The third element of the e-participation is e-monitoring. For Hindman (2009, in Kneuer, 2016), e-monitoring “is based on the assumption that through digital media citizens can not only gain better knowledge of grievances or undesirable developments but also have a stronger voice to express ‘alarm’” (p. 672).

The third dimension of e-democracy is “e-government” which is defined as “the use of ICT (...) as a tool to achieve better government’ (OECD, 2003: 11), in relation to the efficiency of public administration processes, public services for consumers/citizens, to contribute to specific policy outcomes (for example in health policy, environmental policy, and educational policy) or economic policy outcomes like reducing corruption, and to public management modernization” (Kneuer, 2016, p. 669).

III. Digital Participatory Platform (DPP)

1. Definitions

As specified above, “the practice of democracy using digital tools and technologies” is called “digital democracy” (Simon et al., 2017). However, among these digital tools, these authors distinguish the Digital Participatory Platform (DPP) as a specific kind of collaborative social media. In fact, Lee & Kwak (2012) distinguished between two groups of social media based on their main purpose (Kotler et al., 2010 in Lee & Kwak, 2012). The first group “is expressive social media, which enables people to express themselves by sharing with others text, picture, video, and music. Facebook, MySpace, Twitter, Youtube, Flickr, and Foursquare fall into this category of social media” (Lee & Kwak, 2012, p. 492). The second group is considered as a “collaborative social media, which enables people to work together to achieve common goals through interactive and social processes. Wiki and Google Docs are great examples of this type of social media” (Lee & Kwak, 2012, p. 492).

For Falco and Kleinhans (2018a) Digital Participatory Platforms (DPPs) are considered as a specific kind of collaborative social media. They “include all the features proper to ‘conventional’ social media (such as Facebook and Twitter): they are based on Web 2.0, allowing for user generated content, and sharing of such content. However, compared to conventional social media, DPPs also include different and more elaborate technological features ...” (p. 17).

2. Digital Participatory Platform (DPP): Potential and Implications

The majority of the researchers argues that we need more digital tools for actual collaboration and citizen engagement in local government activities (Desouza & Bhagwatwar, 2012; Ertiö, 2015; Williamson & Parolin, 2013; and Zavattaro & Sementelli, 2014 in Falco & Kleinhans, 2018). Indeed, this awareness and this trend were born following the call made by the US. President Obama in 2009 to increase the openness of the government which is based on three main principles: transparency, participation, and collaboration (Executive Office of the President, 2009 in Lee & Kwak, 2012). The open government finds its roots in the advent of the collaborative social media enabling the engagement and the participation of citizens in the government work. In fact, the social media “has changed the public’s expectations about how government work should be done ...” (Lee & Kwak, 2012, p. 492).

The implementation of a Digital Participatory Platform (DPP) takes into account the mandatory use of issues and challenges that local governments face in fostering online and offline citizen engagement (Falco and Kleinhans, 2018). These challenges and issues are seen as a prerequisite to identify actions and solutions for local governments. In fact, what any local government, especially municipality aspire or look for is not only implementing DPP but also how this later should be designed to foster citizen engagement and democracy. Therefore, social media enables the government to become a platform for public participation and collaboration (Lathrop & Ruma, 2010 in Lee & Kwak, 2012).

Wright (2016 in Ranchordás, 2017) claims that digital discussion forums, social media, electronic petition ('e-petition') websites, and several other technologies of participation have the merit of increasing citizen participation and improve the development of the participatory democracy to cope with the perceived crisis in a representative democracy. For Ranchordás (2017) professional digital platforms promote civic engagement and have a huge role in the promotion of citizen participation.

Finally, one can conclude that digital participatory platform has a real potential and a positive impact on participatory democracy and citizen engagement.

3. Digital Participatory Platform (DPP): a Key Factor in Developing Smart Cities

The study of the relationship between the DPPs and the development of smart cities could be explained by focusing on the role of citizen participation and e-participation in their development (Berntzen & Johannessen, 2016; Vrabie & Tîrziu, 2016). The authors stated that developing smart cities could be achieved through citizen participation and e-participation, which is based on the implementation of the DPPs.

For Berntzen and Johannessen (2016) Smart city is considered as "*a label or statement to indicate that the city is actively pursuing use of modern technology to increase the quality of life in urban space, both by improving the environmental conditions and delivering better services to its citizens*" (p. 2). However, a smart city concept could be considered more than a simple label. For Aurigi (2005 in López-Quiles and Rodríguez Bolívar, 2018) "*the smart city concept and other similar concepts such as intelligent cities, virtual cities, knowledge-based cities, digital cities or information cities have emerged on the idea that ICTs is central to the operation of the future city*" (p. 1).

For López-Quiles and Rodríguez Bolívar (2018), the implementation of ICTs in cities is a "*sine qua non*" condition to improve access and efficiency of public services through electronic administration and for improving e-participation as main elements to become smart. Moreover, Erkul (2014 in Vrabie and Tîrziu, 2016) argued that the four pillars of e-participation (greater government transparency, more focus on citizen needs, increased citizen involvement, improved government responsiveness) could lead to the creation and/or development of smart cities.

Thus, the DPPs could be considered as a key factor in developing smart cities (López-Quiles and Rodríguez Bolívar, 2018).

4. Digital Democracy Projects Around the World

This section aims to present some typologies of digital platform projects launched around the world. The authors focused on the empirical study of Falco and Kleinhans (2018), which is consistent with the main subject of this manuscript. There is another empirical study belonging to Simon et al. (2017), very interesting, however, their typology¹ does not correspond to the specificity of the current case study "Baladiaty".

Through a systematic review conducted by Falco and Kleinhans (2018), 113 active DPPs around the world have been identified, analyzed, and classified within a citizen-government relationship typology composed of five digital platforms: (1) *Consulting platforms*, (2) *Interaction platforms*, (3) *Reporting platforms*, (4) *Co-production platforms*, and (5) *Self-organization platforms* (of citizens).

The authors will focus only on three types of them. In fact, their features and objectives correspond to the “Baladiaty” case study. The first is called the *Consulting platforms* “... require citizens to provide their views, comments and preferences through consultations and surveys exist but usually sustain no options for the government to provide feedback, thus lacking an interactive and co-productive potential” (Falco and Kleinhans (2018, p. 9). Among the interaction platforms, Falco and Kleinhans (2018) distinguish “the reporting platforms that facilitate interaction between citizens and the local government on a specific practical issue to be solved (citizens report problems and the local government informs them when it has been fixed)” (p. 9).

Finally, Falco and Kleinhans (2018) found that the “Co-production platforms are also quite widespread with many examples from around the world (e.g. *Block by Block*, *Commonplace*, *coUrbanize* ...” (p. 9). The “co-production” means that the public sector and citizens making better use of each other’s assets and resources to achieve better outcomes and improved efficiency.

BALADIATY: A PILOT DIGITAL PARTICIPATORY PLATFORM IN TUNISIA

The presentation of the different stages followed in order to implement a pilot digital participatory platform (DPP) called “Baladiaty” in Tunisia, is considered as the focal point of this paper. “Baladiaty” is a DPP designed, developed and commercialized by ARSELA in 2019, a Tunisian start-up located in the governorate of Sousse.

1. The Context: The Participatory Democracy in Tunisia: Legal Framework and Perspectives

It is important to note that participatory democracy was anchored in the 2014 constitution² in Tunisia by several articles (Article 31 and Article 32) which address the notion of decentralization and citizen participation on the basis of which an organic law of the code of collectivities was adopted by the assembly of representatives of the Tunisian people (ARP).

Chapter VII of the Tunisian constitution of 2014 was devoted to local power and includes Articles 131, 139 and 140 which were the most explicit on local governance and citizen participation which concerns the partnership between ARSELA and the municipalities.

These articles mark the transitional approach towards decentralization and the strengthening of the process of evolution towards local decision-making to be reinforced by methodological and operational tools to implement. In this sense, the Organic Law of Local Authorities of May 2018 defined, inter alia, the role of civil society as a stakeholder in decision-making at the local level and at different levels of participation and at different stages of municipal works which will now be governed by elected municipal councils. After the first municipal elections of 2018, the new municipal councils moved from the election period to the executive term of municipal works, in order to fulfill the duty for which they had been elected and to satisfy the electors to whom they committed themselves.

In Tunisia, the organic law n ° 2018-29 of May 9, 2018, relating to the code of local authorities, dedicates for the first time the existence of a local decision-making referendum which can be initiated by local authorities or by 1/10 of the community residents participating in community programs and projects. This law also regulates the contribution of civil society to the development and monitoring of local development projects and provides a legal framework for the consultation process for the preparation of development plans. This code is based on the foundations of Article 139 of the 2014 Constitution mentioned above.

The system of local democracy is now hybrid between two types of democracies: representative and participatory. Representative by elected municipal councils that embody a representative democracy based on the election by universal suffrage of representatives of the municipality or local government deliberative bodies in the case of regional and sectorial councils.

Participatory through the involvement of civil society and citizens in decision-making at different levels (information, consultation, and co-decision) and degrees (organizations or citizens) depending on the nature of the projects (administrative, structuring and local). In general, participatory democracy covers different modes of intervention of citizens, individually or through associations, in the elaboration of local decisions.

2. Baladiaty: The Main Features

“Baladiaty” is a technically reliable and ready-to-use solution. It would enable municipalities to join the ranks of smart and innovative cities and move from a fragmented environment to a global and integrated management while simplifying operations and improving services to citizens.

The implementation of the proposed solution is part of a more global approach to digitizing the services provided to citizens to facilitate their relationship with the administration. In fact, the proposed digital solution will make it possible, on the one hand, to improve and simplify access to municipal services by citizens in relation to existing administrative procedures and to facilitate the missions of municipal officials on the other hand.

The “Baladiaty” platform was designed to gather all the tools necessary for effective communication between the municipality and the citizens. It allows to inform, to alert, to exchange, to collect the opinions of the citizens and much more. “Baladiaty” would be an ideal tool to promote good local governance and citizen participation.

In the new context of elected municipal councils, since participatory democracy has been constitutionally imposed since 2014 and supported by the Local Authorities Code of 2018, each municipality wants residents to be constructively involved in local development. By reporting incidents or proposing improvements, the responsible citizen is valued when he is warned that a particular report has been corrected, that his requests have been taken into account.

The number of municipalities in Tunisia is 350. In the context of decentralization, municipalities have free management tools, independent of the ministry, which gives them the possibility to choose management systems specific to their needs as Baladiaty product. The platform has been tagged with the National Authority for Protection of Personal Data to be credible but also optimizes the exploitation of its inputs and their commercialization in the rules of law.

Thus, “Baladiaty” has three strategic pillars of the public value management (PVM) also called the Moore (1995)’s strategic public value triangle³: 1) the definition of the public value 2) the legitimacy and support 3) the operational capabilities.

- Definition of the public value:

Strategic objectives:

- Build a constructive ecosystem and enhance the communication between the municipality and citizens.
- Projects matching with citizens' needs and priorities.
- Agile administrations.
- Attract more stakeholders.
- Make proof and enforce participative democracy and governance.

Strategic results:

- Enhance citizen engagement with their municipalities of at least 60% by 2022 and 80% by 2025.
- Increase citizen's satisfaction towards municipality services and projects of 50% by 2022 and 80% by 2022.
- Boost the trust between the 2 parties 4/5 citizens trust their municipality.
- Decreasing the number of social and solidarity projects/ sustainability projects.
- Bring closer the municipality's stockholders (associations, sponsors, project owners, etc.).
- Becoming a real modern and smart City by 2025.
- **Legitimacy and support**
 - The Tunisian constitution and the laws foster and support participatory democracy.
 - Local community law that pushes municipalities to find projects to empower their own governance.
 - "Baladiaty" is aligned with the government vision of digitalizing the administration services.
 - "Baladiaty" is aligned municipalities mission to improve their services, impact, and communication with citizens.
- **Operational capabilities**
 - "Baladiaty" enables municipalities to join the ranks of e and innovative cities and move from a fragmented environment to holistic and integrated management, by simplifying operations and improving services to citizens.
 - "Baladiaty" will improve and simplify access to municipal services by citizens in relation to the existing administrative procedures and will facilitate the missions of municipal officials.

To determine the value of the platform, the authors will take a closer look at its components. Specifically, the platform has the following three functionalities: (1) Complaints and petitions service; (2) Active Citizenship Space - Survey; and (3) Space of Participatory Democracy - Proposal.

Complaints and Petitions Service

A complaint is the expression of a citizen's dissatisfaction with municipal services. A complaint may also consist of a broken ferry, a defective lamppost, an act of vandalism, it is in fact a malfunction signal within the jurisdiction of the municipality, allowing the municipal team or technical services of the municipality to intervene quickly when an anomaly is encountered on public roads.

The ability to trace geo-located information in a few seconds to the municipality agents represents a considerable asset in the management of a commune, promotes participatory democracy and mobilizes the citizens who can report any dysfunction or problem encountered in the city: pothole, rubbish, lighting problems, bulky objects, abandoned vehicles, defective traffic lights, etc.

The complaints and petitions module should allow citizens to file petitions and complaints (see Figure 2). The solution consists in proposing a form to identify the applicant who is led to make the choice of the type of complaint as well as the municipal service concerned, the seizure of the description of the complaint, to join a proof (photographs, documentation, etc.) and even share his map position.

Figure 2. Baladiaty User Interface - Complaints Service

After receiving a request and complaint form specifying the subject of the request, the municipality is responsible for processing the request and responding to it within 3 to 21 days. The applicant is notified when processing his request through a monitoring dashboard allowing him to access the information related to his request in real-time. This information consists of locating the progress of the processing of the complaint. The solution proposes to provide the staff of the municipality visualization of the report of complaints filed with the municipality on a dynamic map.

Active Citizenship Space – Survey

The solution proposes to provide a space where municipalities can question the population on subjects of their choice and can share the achievements and advancements of their communal projects (see Figure 3).

Before setting up a project for your municipality, it is important to survey the local population to take public opinion into account: how will citizens react? ; What are their expectations, their wishes, and their preferences?

In addition, it could be a future reference database available to the municipality.

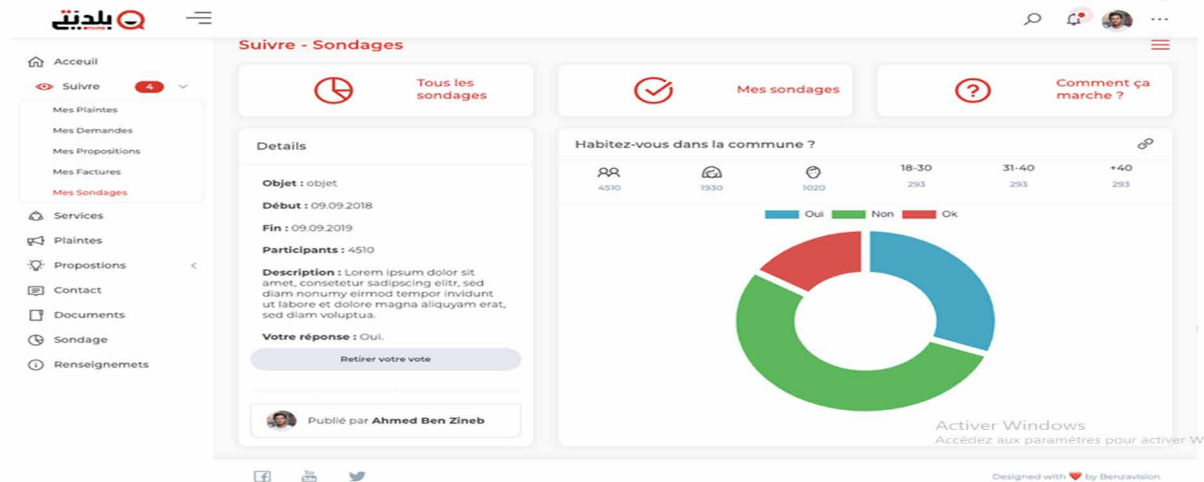

Space of Participatory Democracy – Proposal

Giving citizens the opportunity to suggest an idea to their community allows not only to solve everyday problems but also to make decisions by sharing decisions by bringing leaders closer to the governed.

The advent of new technologies makes it possible to transpose this tool of participatory democracy to digital, and thus allows any citizen user to make a suggestion to his municipality, from his computer, tablet or mobile phone.

Figure 3. Baladiaty Administrator Interface - Active Citizenship Space – Survey

12

The “Suggestion” module should allow citizens to propose project suggestions. It will be generated via the citizen profile of the user. The module will display the number of user evaluations of the platform (commune and citizens) of the shared suggestion.

3. Launch of “Baladiaty”

The platform was adopted by the municipality of Msaken, it was delivered on July 12, 2019 with its user guide and launched online for members of the city council.

The official public launch is scheduled for 17 August 2019 in Msaken during a press conference followed by a communication campaign with citizens who will be invited to download the application and use it. Communication materials have been developed by ARSELA: leaflets, brochures, roll-ups, banners, and billboards. Volunteers will form a door-to-door action that will last three days throughout the town of Msaken. A communication campaign has already been launched on social networks, specifically on Facebook.

The development of a communication strategy dedicated to the launch of the Baladiaty in Msaken helps to set up appropriate communication, identify objectives, clarify the challenges, decide on the reputation and brand strategy that projects’ designers aspire to communicate to the stakeholders of the project and implement and affirm the vision and objectives of ARSELA.

The strategic objectives of this communication strategy are:

- To inform of the existence of an alternative of communication with the commune.
- Trigger the curiosity of the potential user: Give the citizen the desire to discover and browse the features of the platform.
- Creation of a brand image for “Baladiaty” in Msaken.
- Communicate around an image of exclusivity, modernity, and credibility with the aim of consolidating trust and the close relationship between the citizen and his municipality.
- Act: Account creation & use/ownership of the platform by the citizen.

In addition, the project was presented to the Tunisian Confederation of Mayors and the National Federation of Tunisian Cities. ARSELA team obtained an agreement in principle of collaboration that will start by providing the Baladiaty platform to ten municipalities in order to reap the benefits and will allow ARSELA to adjust the solution, promote it nationally and propel it to the MENA (the Middle East and North Africa) region.

4. Baladiaty: The Main Challenges

As a nascent digital participatory platform, and based on an empirical literature review, the authors will present a set of potential challenges that “Baladiaty” will likely face.

Simon et al. (2017) provided a set of challenges faced by three digital participatory platforms implemented by municipal governments. These three case studies, are Decide Madrid (Spain), Better Reykjavik and Better Neighbourhoods (Iceland), and Madame Mayor, I have an idea (France).

The main challenges to overcome are:

- For Decide Madrid (Spain):
 - Financial and human resource requirements,
 - Improving citizen visibility of proposals,
 - Broadening participation and increasing representativeness (Simon et al., 2017, p. 51).
- For Better Reykjavik and Better Neighbourhoods (Iceland):
 - Ensuring breadth of participation and representation,
 - Increasing motivations for participation,
 - Lack of public understanding of the platform and process,
 - Managing resource requirements (Simon et al., 2017, p. 46).
- For Madame Mayor, I have an idea (France):
 - Processing and developing ideas,
 - Finding the right balance of information provision,
 - Generating ideas to address more complex issues,
 - Raising awareness and engagement (Simon et al., 2017, p. 55).

FUTURE RESEARCH DIRECTIONS

Although “Baladiaty” was designed taking into consideration the main features of the best DPPs in the world, the authors are aware that the role of local governments in the success of this pilot project is crucial and strategic. In fact, Spirakis et al. (2010) argued “..., the effect of e-government depends not only on the development of technology but also on the organizational resources and the strategic perspectives” (p. 77). They also argued, “The implementation of ICTs in the public sector can be used as a strategic tool of growth and also as an answer in the current challenges of globalization” (p. 78). Moreover, Falco and Kleinhans (2018) stated “Despite a growing number of web-based and mobile-based platforms that enable information sharing and interaction between government and citizens, scholars have highlighted that use of DPPs is not yet interactive and is not being able to create two-way communication (Williamson & Parolin, 2013; Ertio, 2015)” (p. 4).

Therefore, the main question to answer is how local government will overcome these challenges if they exist. In addition, do local governments face specific challenges? How to measure the impact

of “Baladiaty” on local participatory democracy and citizen engagement in a nascent democracy like Tunisia? What role do technology and networks play in governance? How do they affect traditional structures and organizations? What about public value? What is the nature of the relationship between crowdsourcing and digital participation as a pillar of digital democracy? Etc.

CONCLUSION

This paper belonging to the topic of electronic government aimed to present the implementation of a pilot digital participatory platform (DPP) called “Baladiaty” in order to foster local government-citizens collaboration and participation in Tunisia. However, it is obvious to note that the description of the single Tunisian experience (“Baladiaty”) cannot produce a valuable generalization concerning the role of e-democracy, digital participatory platforms and their impact on collaboration between local government and citizens.

Although this article presented a pilot digital participatory platform in a nascent democracy (Tunisia), it could be considered as a very rich theoretical manuscript in which the authors introduced and defined various basic concepts in the field of public management, namely: democracy, e-democracy, representative democracy, participatory democracy, e-participation, e-government, DPPs, etc.

As explained all over this manuscript, the implementation of a digital participatory platform has a critical and strategic perspective not only for governments or for local governments (e.g. municipalities), but also for policymakers who will improve the sense, practice, and meaning of democracy for all the citizens. Hence, all the concepts described here have a strategic role in the relationship between new participatory models and their impact on collaboration between local government and citizens.

KEY TERMS AND DEFINITIONS

DDP: A kind of social media. It is considered as a collaborative social media.

Direct Democracy: A form of democracy in which citizens play a direct role in political decision-making without intermediaries.

E-Democracy: Also called digital democracy. It is defined as the practice of democracy by using information and communication technologies.

E-Government: It is defined as the use of digital tools for exchanging information, providing services and transacting with citizens, businesses, and the rest of the stakeholders.

E-Participation: Is one of the e-democracy dimensions. It is related to e-government and e-governance. It is about fostering citizen's engagement.

Participatory Democracy: It is defined as the involvement of citizens in decision-making on public policy.

Representative Democracy: Also called indirect democracy. It is the contrary of the participatory democracy. People elect officials or government representatives to handle legislation and ruling the country on their behalf.

- ³ “Moore (1995)’s strategic public value triangle is based on three concerns that must be faced by political leaders and public service managers. First of all, the definition of public value, concretely clarifying the objectives and purposes of the services that must include the production of value not only for the individuals directly affected but also for the communities concerned, which implies making the link between the user and the citizen and to appeal to the deliberation since the public value is plural and that it is never defined once and for all. (...) Secondly, the concern for the public value cannot be realized without an authorized and legitimate environment since it is necessary at the same time the support of the public authorities and the construction of a coalition of the stakeholders (users, communities, private sector, public sector, voluntary sector) with diversified interests. Thirdly, the operational capacity to build goods and services is required, which refers to the feasibility in terms of mobilizing operational resources (financial, personal, skills, technology) inside and outside.” (Lévesque, 2014, p. 9).

Local Government, Decentralisation, Devolution, and Service Delivery in Zimbabwe

12

Tawanda Zinyama

University of Zimbabwe, Zimbabwe

INTRODUCTION

Zimbabwe is one of only a handful of countries in sub-Saharan Africa that have taken part in the wave of decentralization and devolution. The process differs from the efforts of the 1980s, 1990s and 2000s in that this time the government of Zimbabwe seems ready to relinquish genuine power to the subordinate levels. Devolution of power is enshrined in Zimbabwe's 2013 Constitution as one of the country's founding values and principles. However, as was the case with in the 2000s, it is sometimes easy to romanticize about the benefits of devolution and fail to take into account the detailed work required before it benefits people at the local level. The devolved administrations exercise considerable autonomy when it comes to tackling poverty: for instance, major areas of economic development, education, health and housing policy are the responsibility of the devolved institutions.

This paper seeks to address the following questions: in what ways can devolution contribute to socio-economic and greater welfare of the people? What are the principles guiding decentralization and devolution? What are the ideal institutional frameworks for Provincial and Metropolitan Councils? How are these Councils going to raise and collect revenue? Will the devolution address the regional injustices and marginalization? Is there shared understanding of devolution in Zimbabwe? The paper is organized into five sections. First section provides the background and conceptual framework. Section two presents Zimbabwe's local government system focusing on the rationale, objectives and principles of devolution, innovations of the local government and planning as an instrument of social mobilization. Section three focuses on constraints on local governance such as lack of citizen consultations, unitary state, slow pace of legislation alignment, center-local relationships and violation of legislation among others. The fourth section covers solutions and recommendations such as assistance and support, public finance management system, politicization of local governance in Zimbabwe, civic culture creation and multi-stakeholder participation. The fifth section presents the future research directions. The last section provides a conclusion.

BACKGROUND AND CONCEPTUAL FRAMEWORK

Decentralization and Devolution

Interest group politics suggest that politicians at the center have little wish to cede their vast powers, notably those over public finances, to the local level. They embark on meaningful local reforms, including decentralization and devolution, only when they sense authentic benefits to themselves and their

DOI: 10.4018/978-1-7998-3479-3.ch109

political supporters from incorporating the local government into the mainstream political process, for example, when this gives them a political advantage over their competitors at the center or when, to generate welfare-enhancing growth, create broader markets (Zinyama, 2019; Chigwata, 2018) for urban-based industries or support the agricultural activities of the elite, it becomes necessary to liberalize the economy as well as domestic politics.

Decentralization is a generic term for the diffusion of governmental authority and power away from the national center to other institutions at other levels of government or levels of administration (Moyo and Ncube, 2014). Devolution is generally classified as the most extensive form of decentralization that diffuses substantial governmental powers, authority, responsibilities and resources to local units. Such units exercise a measure of autonomy, which is “the extent to which local governments have discretion in carrying out their duties and obligations” (Masunungure and Ndoma, 2013; Chigwata, 2019). However, such autonomy cannot be equated to the independence enjoyed by a sovereign State, given that local units exercising devolved powers are not at par with the central government. Unlike federal systems where the regions or provinces maintain their own independent power and cede or receive some authority to or from the federal government, devolved units do not occupy the same sort of position in relation to the central government (Chigwata, 2019). The dimensions of devolution include centralization, administrative, fiscal, political, delegation and deconcentration (Barnett, et al. 1977; Poverty Reduction Forum Trust, 2019). Devolution aims to create local governments that are independent, autonomous and usually have exclusive authority over explicitly defined functions. Political autonomy is meaningless if it is not accompanied by fiscal autonomy, which entails the ability to raise and spend revenue (Moyo, 2013; Chigwata, 2018).

ZIMBABWE’S LOCAL GOVERNMENT SYSTEM

Local government is recognized in Zimbabwe as an important tier or sphere of government closet to the people, capable of providing a participatory and accountable style of governance for local communities (Zinyama, 2019, Chigwata, 2018; Moyo, 2013). It helps to provide service provision to communities in an equitable and sustainable manner. Chapter 14 of the Zimbabwe Constitution (2013) provides the framework for devolution of governmental powers and responsibilities in Section 264. Likewise, in Section 5 of the Constitution, the tiers of government provided are the national government; provincial and metropolitan councils; and local authorities. Since the adoption of the 2013 Constitution, the government has not yet crafted legislation to devolve power to Provincial and Metropolitan Councils.

Sections 268 and 269 of the Constitution of Zimbabwe establish Provincial Councils and Metropolitan Councils respectively. The Provincial and Metropolitan Councils are a middle and critical link between government and citizens.

Section 270 of the Constitution requires Provincial and Metropolitan Councils to undertake social and economic development in their respective provinces, including:

- planning and implementing social and economic development activities in its province;
- coordinating and implementing governmental programs in its province;
- planning and implementing measures for the conservation, improvement and management of natural resources in its province;
- promoting tourism in its province, and developing facilities for that purpose;
- monitoring and evaluating the use of resources in its province; and
- exercising any other functions, including legislative functions, that may be conferred or imposed on it by or under an Act of Parliament.

Devolution Rationale

A number of factors have contributed to the highly centralized state structure in Zimbabwe though having a good track record of representative democracy. Firstly, colonialism bequeathed a historical legacy of centralized government. Secondly, social and economic crises since late 1990s have been powerful stimuli for centralization. Thirdly, powerful political and bureaucratic vested interests have consciously thwarted attempts to fully decentralize and devolve power. Fourthly, successful decentralization requires certain pre-conditions (Zinyama, 2019; Chigwata, 2018; Moyo, 2013) such as an appropriate legal and administrative framework, a local information base, capacity-building programs and civic culture. To make the fulfilment of these pre-conditions a requirement for introducing democratic decentralization can become an argument for postponing devolution of powers to the lower levels.

Devolution is, therefore, seen as a necessary vehicle for doing away with the over-centralized system of government, deepening democracy, promoting locally driven development, improving the delivery of public services, and promoting national integration and peace while recognizing diversity. However, the concept of devolution is very contentious, emotive and divisive with strong regional overtones in Zimbabwe (Masunungure and Ndoma, 2013). It is also a frequently misunderstood and sometimes deliberately distorted term (Ibid.). For example, former President Robert Mugabe thought devolution would divide the country into small pieces and cause disunity. His argument was that:

Those things are done in big countries, not a small country like ours.... Some are talking about separating Matabeleland region to become a country, that is impossible we don't want that (Newsday, 14 March 2012).

However, the late then Prime Minister, Morgan Tsvangirai disagreed with Mugabe:

Devolution does not mean secession. It does not mean separation; it is not about tribalism. It is about sharing the national cake equally (Masunungure and Ndoma, 2013).

What then has changed to justify the current optimism regarding the developmental impact of decentralization and devolution? Three factors can be noted in this regard. First, decentralization, at least in theory, holds great potential for development. It can be said to possess a dual mandate. Decentralized government provides space for people to participate in the formulation of policies that affect them directly, including the setting of local taxes, provision of social services and ensuring security of life and property (Zinyama, 2019). It is also assumed that it is easier to exercise inclusive politics, which enable communities and groups to influence policies that affect their daily lives, at the local than at the national level. Indeed, for many aid agencies, local participation has become the focus of their aid programs. Besides, decentralization and devolution are assumed to improve decision-making at the local level and to raise the quality of governance. Also, by encouraging local participation, decentralization and devolution enhance resource mobilisation, including development aid and ensure a more efficient use of resources. This increases the production of goods and services and, thus, local welfare (Bossuyt and Gould, 2000).

Second, the growing rural-urban divide in Zimbabwe and the undemocratic provincial structures have condemned the majority of the masses to unending poverty and wretchedness – without basic education, healthcare, shelter and nutrition – the alternative being migration to the squalor of city slums. The current power pyramid needs to be reversed. Everything that can be decided and implemented optimally at the local level should be kept at that level leaving the rest to be taken at national level. It is also necessary to move beyond the confines of representative democracy. Forums must be created so that the ordinary

citizens can directly intervene, deliberate and decide in the governance and development processes. Democracy, from being a ritual of periodic elections, needs to be extended to grassroots level.

Third, democratic decentralization and devolution are an important political response to Zimbabwe's development crisis. The expectation is that devolution accelerates socio-economic growth and creates a new model of growth with equity. Democratic decentralization can contribute to improvements in efficiency of implementation, particularly if the development process is made participatory and transparent. This helps prevent misuse of resources and allows for better monitoring of programs. Participation can also help in tapping dormant local resources in the form of monetary donations, material contributions and voluntary labor (Zinyama, 2019). In labor-surplus communities with disguised unemployment, community participation can mobilize significant contributions of human resources to create social and physical infrastructure (Ibid.).

The Objectives and Principles of Devolution

Section 264(2) of the Constitution provides the objectives of devolution. Devolution is necessary to “give powers of local governance to the people and enhance their participation in the exercise of the powers of the State and in making decisions affecting them” (Government of Zimbabwe, 2013). It seeks to promote democratic, effective, transparent, accountable and coherent government. Given that Zimbabwe is an ethnically diverse country, devolution is important to preserve and foster the peace, national unity and indivisibility of Zimbabwe. While there is nothing wrong with nationally led-development with respect to ‘national issues’, devolution is a means of “recognizing the right of communities to manage their own affairs and to further their own development” (Ibid.). If properly designed, devolution can ensure the equitable sharing of local and national resources. For locally driven development to have a higher chance of success, devolution is necessary to transfer responsibilities and resources from the national government in order to establish a sound financial base for each provincial and metropolitan council and local authority.

The objectives of devolution are supported by the general principles of provincial and local government enshrined in section 265 of the Constitution. The Constitution requires these local governments to exercise their functions in a manner that does not encroach on the geographical, functional or institutional integrity of another tier of government. They are encouraged to “cooperate with one another, in particular by (i) informing one another of, and consulting one another on, matters of common interest (ii) harmonizing and coordinating their activities” (Ibid.). While they are not hard rules, these principles demand positive action from provincial and local governments.

These functions are vague and ambiguous. They are a mere framework and understandably so because the crafters of the Constitution would not have expected to specify the functions in the Constitution for purposes of brevity. There is need to specify how central government functions such as education, health, roads, electricity provision, land-use management, licensing, transport and registry among others are to be shared between central government and Provincial Councils.

However, the Constitution does not define what socio-economic development entails. It is not clear whether this includes the power to adopt policies and spend budgets on matters that relate to socio-economic development. In general, socio-economic development encompasses almost everything, from social related services, such as, the provision of health, education and sanitation, to economic orientated activities including tourism, natural resources extraction and job creation. Legislation and policies that clarify the parameters of the socio-economic development function of the councils, among other things, is required.

Innovations of the Local Government in Zimbabwe

The Zimbabwean government sees the devolution of power as a key means of introducing popular democracy and fostering local governance. This promotes capacity building at the local level and ensures that there are local inputs in the decision-making process, especially with respect to service delivery. These factors would in turn help foster a local sense of ownership of development programs. The devolution is enshrined in the Zimbabwean Constitution of 2013, with amendments made to the Provincial Councils and Administration Act [Chapter 29:11] which spells out the mechanisms of decentralization and devolution. The amendments have been prompted by the need to align the current Provincial Councils and Administration Act [Chapter 29:11] with the provisions of the Constitution of Zimbabwe which advocates for the devolution of power to Provincial and Metropolitan Councils.

Devolution in Zimbabwe: Goals, Policy Innovations and Outcomes

What impact would these far-reaching interventions would have on local government's ability to deliver services and to what extent would local populations be involved in the running of their affairs? The main goals of decentralization and devolution process in Zimbabwe, along with policy innovations intended to achieve results are as follows.

Table 1.

Goals	Policy Innovations	Comments on Outcomes
Involvement of local people in the management of their own affairs	Identify local problems and find solutions to be implemented by locally elected organs	Raising local people's interest in the management of their affairs is probably the strongest outcome of devolution effort in Zimbabwe
Democratization of the decision-making process	Elect local leaders instead of having them appointed by central government Planning as an instrument of social mobilization	Local level democracy is taking longer to take hold, probably for lack of precedent. Equitable socio-economic development
Mobilisation of local resources	Make budgets and prioritise expenditure according to needs at the local level	Few local governments are financially independent from the center and they continue to be beholden to government
Reduction in costs for service delivery	Improve social infrastructure and expand social service provision in the countryside	Scarcity of resources makes the undertaking of extensive infrastructure and service extensions difficult Poverty reduction and improved living standards
Improved efficiency and accountability at the local level	Enhance human resources by appointing professional staff to run local services.	The quality of staff recruitment at the local is improving though lack of resources implies that many are not filled. Budgets should be used as management tools. The central government uses the budgets to monitor and evaluate the budgetary and financial management performance of provincial councils. Streamlined budgets facilitate frequent audits of financial statements.
Peace Promotion and Conflict Resolution	Establishment of National Peace and Reconciliation Commission Outreach programs for publicity	Territorial justice Development and democracy National integration and peace

Brief discussions of these goals follow.

The empowerment of local populations by involving them in the identification of their problems and the finding of solutions should be the driving feature of devolution in Zimbabwe. Local councils are composed of elected local people, who often hold personal stakes in the welfare of the province. Such individuals are expected to have considerable interest in the deliberations of the councils and to defend the interests of their constituencies against, for example, the demands of the central government. Some regions such as Matabeleland, Masvingo and Manicaland may start feeling that they are getting a fair deal in terms of access to resources. Furthermore, the devolution program, by involving hundreds of thousands of people, hitherto totally ignored, in the political process at the local, may stimulate a rapid growth in social responsibility and political creativity. This may increase the involvement of women and youth in local politics.

Democratization of decision-making: through local councils, the powers and responsibilities for making decisions over issues of local concern in the province would be democratized. This represents a fundamental shift from the traditional procedure where policies implemented at the local level were made by state bureaucrats based in the capital city and, thus, far away from the people affected by those decisions. This will help communities reach consensus on political and development issues. This is because the devolution system moves away from the unbridled and comprehensive subordination of locality to center of the past to a relationship steeped in consensus building, participation in policy formulation and negotiation. Increased transparency in local government would improve the stakeholders' capacity to expose the practices of malfeasance and corruption, which in the past often went undetected at the central level and to initiate corrective action.

Mobilization of local resources: proximity to local policy-makers would increase tax compliance, because the population not only would be able to see the direct benefits, in terms of improved services, but also would be able to monitor the use of resources and, via the provincial councils, hold errant officials accountable for abuse of office.

Improvement of service delivery: resource mobilization is closely related to the local government's capacity to improve service delivery. Local councils have assumed a number of functions that were previously performed by line ministries. These include political administration, monitoring and supervision of development projects at the local level and maintenance of community roads. However, not all local governments have the financial or human resources required to provide an adequate level of services. At the lowest levels, much of the work is done by ward councilors. Due to lack of skills, ward councilors poorly facilitate developmental activities.

Efficiency and accountability: lack of transparency and, indeed, corruption are among the spurs for faster devolution. However, part of the reason corruption and abuse of office are so widespread at the center are poor managerial capacities. Devolved corruption should be avoided. This would be especially true where local administration capacities are weaker than at the center. The central government can curb corruption through the use of intergovernmental transfers governed by objective criteria. Conditional grants are disbursed when the local governments fulfil the agreements with the central government regarding certain targets, such as recruiting teachers, purchase of drugs or provision of extension services. These grants may cover recurrent expenditure, whereas unconditional grants cover local capital expenditures. Second, funds for local government operations should not be routed through line ministries. Instead, the Treasury has to remit funds direct to the accounting officer of each provincial and metropolitan province. An innovation would be that the amounts disbursed are published in local newspapers. This would enable the local populations to know what to expect in terms of service provision and acts as a deterrent to financial abuse.

Peace promotion and conflict resolution: devolution addresses territorial grievances. The grievances range from differentiated patterns of income and unemployment to poor infrastructure and low business or economic activity. A major consequential benefit of devolution, therefore, is an “economic dividend” that accrues to regions or territories that are perceived to be disadvantaged by centralized models of development. Devolution is, therefore, a mechanism that facilitates the attainment of territorial justice (Morgan, 2006; Moyo, 2014).

In Matabeleland, there are examples of the Hwange Thermal Power Station and the Kariba Hydro-Electricity Power Station. The majority of the schools and homes in the surrounding Hwange, Kariba and Binga districts have no electricity, yet these two major electricity power stations generate and supply a lot of electricity to the national grid. Furthermore, “three of the country’s busiest border posts (Beitbridge, Plumtree and Kazungula) that remit high amounts of revenue to the state” as well as “several tourist resort centers such as the Victoria Falls, Hwange National Park and Matopos, which similarly remit the highest amounts of foreign currency to the state” (Mhlanga, 2012) are located in Matabeleland provinces yet this region remains one of the poorest and least developed. Given these imbalances and inequitable distribution of revenue derived from exploitation of national natural resources, it is not surprising that calls for devolution were more prominent in these marginalized provinces which anticipated territorial justice through devolution.

Planning as an Instrument of Social Mobilization

The distinctive feature of decentralization and devolution in Zimbabwe is the central role allotted to the planning function of the Provincial and Metropolitan Councils. A comprehensive Provincial and Metropolitan plan is to be prepared by each body before it can claim the grant-in-aid. The planning process starts at the grassroots with maximum involvement of the masses. Mass participation is not limited to elected representatives or voluntary agencies, but includes ordinary people assembling in districts with non-official experts and volunteers participating in preparing reports, formulating projects and drafting plans. Officials are to work alongside non-officials. In order to ensure transparency and participation without compromising technical objectivity, a sequence of phases each with its distinctive objectives, main activities and training program should be drawn up. Mere listing of needs does not make a plan, the resources potential for satisfying them has to be assessed. The second stage may start with a number of participatory studies of the problems and assessment of the local resources, both human and material. The findings of such studies and the deliberations in the districts should be summed up in a development report. Planning is a technical process that involves assessment of needs and resources, fixing of priorities, preparation of projects and formulation of plans. In Zimbabwe, decentralization and devolution planning process should be used as more than technical exercises. They should be used as instruments for social mobilization in support of devolution. The mass mobilization must be intended to ensure that the correct decisions are made at the local level, to bring about certain attitudinal changes among participants and to build up mass pressure from below for democratic reforms.

Devolution Fund Allocation Guidelines

The Constitution recognizes the need for equitable revenue sharing among the tiers of government. It provides for the transfer of fiscal resources from the national government to Provincial and Metropolitan Councils (PMCs) and local authorities. Section 301(3) of the Constitution of Zimbabwe states that not less than 5% of the national revenues raised in any financial year must be allocated to the province and

local authorities as their share in that year. This requires the Ministry of Finance and Economic Development to consider annual revenue projections and determine the percentage allocations to PMCs based on such factors as the population size, poverty levels, infrastructure deficits, socio-economic disparities, national development goals and priorities among others. In addition, Section 301(1) of the Constitution directs Parliament to enact legislation providing for conditional and unconditional grants to PMCs and local authorities. The other imperative for devolution is to share the national cake equally amongst Zimbabwean citizens. The Constitution sets the criteria that inform the allocation of conditional and unconditional grants to provincial and metropolitan councils and local authorities. The devolution policy being crafted by government must spell out the formulae for the allocation of funding to the provinces so that all the regions equally benefit from national resources. However, a comprehensive revenue sharing model should not only be influenced by political parameters. The financial and economic considerations have to be made in determining the weight of population, infrastructure gaps and/or economic disparities in setting the fiscal formulae for revenue sharing in which case, the different provincial and local councils will be funded commensurate to their fiscal needs, effort and gaps.

The Public Finance Management Act needs to be amended to facilitate the allocation of sufficient resources for basic social services and economic development at the local level. The need to implement devolution has subsequently been echoed in various government policy documents. For instance, the Transitional Stabilization Program (TSP) (Government of Zimbabwe, 2018). The TSP provides various measures which the government seeks to implement to change the socio-economic environment in order for Zimbabwe to attain the status of a “prosperous and empowered upper-middle income society by 2030” (Government of Zimbabwe, 2018). A key feature of this plan is devolution of governmental powers, responsibilities and resources with a key focus on provinces. A section of the plan titled *Empowerment of Provinces* reads:

While Zimbabwe remains a unitary State, the implementation of the country’s development programs will allow for devolution to achieve fair and balanced development, spearheaded by Provincial Councils which will initiate development programs for their respective Provinces, consistent with Section 264 of the Constitution (Government of Zimbabwe, 2018).

This represents a new governance framework where decentralization becomes a key feature and strategy for fair and just governance across its four dimensions, namely administrative, political, fiscal and market.

These reforms focusing on the provincial level and devolution at large were also recognized in the 2019 Pre-Budget Strategy Paper published by the Ministry of Finance and Economic Development. The Paper emphasizes the need for local authorities to begin to be more visible in the delivery of services and investment promotion. The fact that the blueprint and the Pre-Budget Strategy Paper were relatively talking to each other, is indicative of the fact that there is the political and administrative will to implement devolution. The 2019 national budget speaks to devolution and the operationalization of provincial councils. The national government allocated US\$310 million to provincial councils in the 2019 financial year as part of the five percent Provincial Councils are entitled to in each financial year. It is not clear whether the omission of metropolitan councils was deliberate, or, whether they were, indeed, factored into this allocation. The actual allocations to provinces require Cabinet approval to ensure that these allocations “target addressing pockets of marginalization in Provinces and Districts” (Government of Zimbabwe, 2018). This requirement is without doubt an indication that while provinces can determine their own development priorities, it is the national government that has the final say since Cabinet can

veto expenditure prioritization proposed by a province. This does not augur well for the principle of devolution, which entails diffusing policy making and implementation powers, including over expenditure decisions, to the local level. These issues need to be clarified in the decentralization and devolution law and policy reforms.

CONSTRAINTS ON LOCAL GOVERNANCE

A fully devolved local government presents an opportunity to solve a number of problems that have been noted within the service delivery system of the country. Some of the challenges noted include too much central governmental interference in local authorities, lack of capacity issues and skills, limited financial resources, lack of accountability and poor management of public services both in the central and local government. However, there are challenges that can undermine Zimbabwe's capacity to implement devolution as enshrined in the Constitution. These are discussed below.

Lack of Citizen Consultations

Local governance can make meaningful impact on people's lives if local communities are given space to participate and provide views on the type of local governance they want. The government is still to give Zimbabweans an opportunity to shape the devolution narrative through devolution discussion.

Unitary State

Historically, Zimbabwe is known to be a unitary state and important decisions on local development have been taken care of by few people mainly from the central government. This poses a serious challenge on the political will to devolve the local development.

Lack of Resources Leads to Program Failure and Reduce Independence

Lack of own resources is probably the single most important impediment to local governance in Zimbabwe. It may limit severely the extent to which local leaders can deliver on their electoral promises, notably improvement of social services, and limits their ability to resist demands and interference from politicians at the center as well as those from line ministries. With their independence, thus, curtailed and lacking their own funds, local governments run the risk of becoming instruments for the propagation of political schemes or for the exercise of patronage by politicians at the center. Lack of resources also limits the extent to which local leaders can motivate their staff and retain them in the now stiff competition between the public and private sectors for educated and efficient employees. A shortage of skilled staff may put a limit on the amount of intervention that local governments can embark on successfully. It also implies that important aspects of accountability, for example, keeping the books in order, refining policies or designing new ones, cannot be undertaken easily. Given that Zimbabwe's educated labor force has expanded substantially since independence, the problem of skills shortage might be resolved when local government design more attractive terms of service, including improved remuneration.

Another concern is on the dwindling revenue base of local authorities with state institutions such as Zimbabwe National Authority (ZINWA), Environmental Management Agency (EMA) and Zimbabwe National Road Agency (ZINARA), taking much of the financial resources that should be going to local

governments in revenue. This raises questions on the sustainability of the financing mechanism to back the process of devolution.

The lack of resources causes a serious shortage of supplies, equipment and physical structures, making daily operations difficult and the realization of policy targets all but impossible. Although lack of basic facilities and tools is partly a result of serious under-capitalization in past decades, the social infrastructure including schools and clinics, destroyed, making their situation more precarious today. Children are still taught under trees in some areas and local government offices are often derelict structures.

Slow Pace in Legislation Alignment

Despite the constitutional provisions that oblige the government to devolve the local governance structures, there is lack of political will from the government's side to enact Acts and legislations that confirm to the constitution's view of devolution. The Urban Council Act [Chapter 29:15] gives excessive powers to the Minister of Local Government and there is too much regulation and interference of the Minister in the operations of the local authorities. The current laws namely the Urban Councils Act and the Rural District Council Act are not aligned to embrace devolution as spelt out in the Constitution.

Center-Local Relations Remain Complex

The central government's wish to control the periphery made nonsense of many earlier attempts to cede powers to local authorities. Direct coercion, including legislation was often necessary to restrain the clamor for autonomy at the local authority level. To what extent, then, the devolution strategy, based on PMCs, would reduce the tension between the center and the councils in matters of policy coordination, budgeting and accountability? The devolution policy should not be hurried, with little preparation of stakeholders, notably the local populations. This may leave considerable room for discretion to politicians. Policy opacity at the local level may make it difficult for the local population to internalize the devolution system. Since the new systems' credibility is depended to a large extent on local people's reaction to its provisions and their ability to penalise poor performance, it is imperative that they understand the issues involved. Devolution threatens various interest groups including politicians. Indeed, whenever there are changes in the political and administrative system there is bound to be resistance and sometimes apathy. These reactions do not mean that change promises little benefit to the population. Since it introduces new ideas and policies and alters the way things are done, change might be the key contribution of devolution development.

But perhaps the most important source of conflict between center and local councils relates to money. Needs-based formula for sharing the national cake needs to be considered. This must take into account the capacity of regions to collect taxes, a degree of inequality in resource distribution remained. The equalization grant is to be based on assessment of resource endowments, with poorer provinces compensated accordingly. However, for the system of transfers to succeed in achieving the goals envisaged by the center and the local government, there is need for a high degree of accountability. This can be achieved through production of monthly accounts of expenditure for purposes of planning and budgeting to the center (Ministry of Finance). Use of threats should be encouraged. The Ministry of Finance must try to reconcile the budgetary process at the center by resorting to threats including withdrawal of funding from provinces not complying with its directives and publishing a list of such provinces in the local newspapers. With devolution, departments in line ministries are also supposed to reduce their functions to those of policy making and supervision, relegating operations and related expenditures to the provincial councils.

Violation of Legislation

The President appointed Provincial Ministers, a move that is in contradiction with the Constitution. There is no constitutional provision that sanctions the appointment of provincial ministers and it is not clear what their duties and responsibilities are. A key question is raised around the operationalization of the provincial councils considering there is going to be an executive minister for the province. It is not yet clear what role these ministers will be playing in light of the provincial councils that the constitution talks to.

SOLUTIONS AND RECOMMENDATIONS

Assistance and Support

Training and capacity building are crucial for successful implementation of decentralization and devolution. Like any other process that seeks to change the status quo, devolution, therefore, requires education. Devolution education is necessary for officials both at the national, PMCs, civil society actors and the general citizenry in the areas of legislation, policies and institutional framework. There is need to enhance capacities of both local community leaders, councilors and their council employees. For example, there is need to carry out capacity building exercises on the duties and functions of councilors. There is also need to strengthen the supply side of local governance through council human resources audits, skills retooling so that it is able to adequately perform its duties.

Public Finance Management System

Sound public finance management systems are a pre-requisite for devolution to be a success and to be meaningful. If the implementation of devolution is hurried without sound public finance management systems, more problems may be created than it seeks to address. When designing a multi-level system of government, it is vital to ensure that there are specific rules, mechanisms and institutions to provide the accountability of various governments to the citizens. Such mechanisms may include independent oversight committees, reporting systems, timeous and easy access to information. Furthermore, the mechanisms include approval of resolutions of PMCs, monitoring visits, performance checklists; for example, service delivery, budgets, compliance, corporate governance and capacity to generate and utilize revenue (Zinyama, 2019).

There is need to have a comprehensive financial monitoring and reporting system. Section 298(1) of the Constitution of Zimbabwe requires clear fiscal reporting at all levels of government. In terms of Section 35(7) of the Public Finance Management Act, within 120 days of the end of the financial year, every provincial council, metropolitan and local authority must submit to the Minister: a) an annual report; b) audited financial statements; and c) the audit report. Training, therefore, becomes a critical component in upgrading competencies and skills of both staff and members.

There is need for political will to address weak internal controls, poor corporate governance, procurement irregularities, and inadequate controls in receipting payments and meeting statutory obligations and deadlines for financial reporting which are recurrent in the successive Auditor General's reports. Without political will to implement punitive measures on errant local and central government officials, the inherent benefits associated with devolution will remain conjectural and theoretical. The first step, therefore, is to enforce the implementation of Section 299(1) of the Constitution regarding the role of

Parliament to monitor and oversee provincial and metropolitan councils as well as local authorities through the alignment of the Public Finance Management Act to the constitution and the promulgation of an Act of Parliament to operationalize devolution. The proposed Act of Parliament should be clear on the obligation of local governments to submit annual budgets and financial performance reports to government, Auditor General and Parliament of Zimbabwe. Such provisions should also incorporate provisions that establish institutional and administrative frameworks that are used by Parliament in monitoring and overseeing state revenues and expenditure.

Politicization of Local Governance in Zimbabwe

There are high levels of infiltration of politics in local governance systems to such an extent that it is difficult for duty holders who are political leaders to dialogue with residents on development issues in a progressive and accountable manner. Failure to address this challenge might affect Zimbabwe's capacity to deliver genuine devolution.

Civic Culture Creation is Fundamental

The PMCs must actively seek to nurture a civic culture that promotes grassroots democratic institutions. A radical transformation of the development culture of the state is a necessary pre-requisite for successful participatory decentralization. It also requires basic attitudinal changes towards the development process among all the key players involved: the elected representatives, officials, experts and the public at large. The bureaucratic departmental approach to development has to give way to an integrated and democratic vision. The ivory tower attitude and deeply ingrained cynicism prevalent among the technical elite will have to be replaced by a culture of participation and engagement. There has to be a transformation in the mindset of the elected representative themselves. Mindset of centralism often stays rooted in the attitudes and behavior of the PMCs beneficiaries, with local authorities appearing tentative and apprehensive in exercising their governance powers.

Political and Administrative Will

Devolution shakes people's comfort zones and the traditional lines of distributing power and resources. Devolution is often a difficult and contested process throughout the world. However, with sufficient political and administrative will, devolution can be implemented.

Long-term Strategy for Devolution Implementation

Evidence throughout the world shows that the implementation of devolution is not an event but an on-going process. The implementation process takes time, requiring review and adjustments from time to time. Importantly, the implementation of devolution requires the backing of the ordinary citizens to ensure sustainability. There is need for think-tanks and academics to continuously inform the process. There is need for a strong center to deliver funding, technical expertise and co-ordination.

Multi-stakeholder Participation

Public participation is *sine quo non* for successful decentralization and devolution. All interested stakeholders including relevant government departments, civil society, residents' associations, PMCs, elected political leaders, church leaders, women organizations, youth organizations, private sector organizations and citizens at large must participate. There is need to develop performance management tools for community leaders, councilors and ministers. The following public participation infrastructure needs to be in place:

Public participation policy: There is need for a consultatively developed policy and framework to guide the public participation process at the Provincial and District levels. This helps to move away from tokenism to real, genuine and effective participation.

Citizen capacity and awareness: both Provincial and Metropolitan Councils must create awareness and capacity build citizens on their rights; and the available opportunities for participation in public financial management. This enhances the quality of inputs from the public in key policy documents such as provincial plans and budgets.

Timely disclosure of information: for fiscal transparency and public participation to be realized, regular and timely disclosure of fiscal data such as strategic plans, budgets, fiscal forecasts and budget monitoring reports among other relevant documents is important. These should be prepared in a simple and clear language for the public.

Timeliness and agenda: The purpose for public engagement should be publicized in advance. The Provincial and Metropolitan entities must clearly specify the scope and agenda of the consultation. The public must be given enough time to internalise the subject matter and develop their submissions. Best practice requires that the notice is given between fourteen (14) and twenty-one (21) days.

Feedback mechanism: The Public should be provided with feedback on their inputs. This requires Provincial and Metropolitan Councils to publish reports of the inputs received from its public consultations and explain how these inputs have been used or otherwise in budget decisions, execution and oversight. Civil society organizations should develop monitoring and evaluation tools for feedback and accountability measurement.

Budget allocation: Provincial and Metropolitan Councils need to budget for public participation. Such allocation assists in awareness creation for meaningful participation.

Thus, the government should support wide consultations in the type of devolution that can work given Zimbabwe's operating environment. There is need for national multi-stakeholder conferences to sensitize and consult citizens on devolution.

Intergovernmental Relations

The structures and processes that governments develop for intergovernmental consultation, co-ordination, and co-operation are referred to as intergovernmental relations. Since Zimbabwe has adopted multi-tiered governance systems, it is necessary that the levels of government communicate with each other. No matter how carefully the powers and responsibilities of each level of government are specified, it is inevitable that there will be areas of overlap in virtually all policy fields. The actions of one government affect other governments. As governments attempt to pursue rational, coherent sets of policy priorities, they realize there is a need to co-ordinate their contacts with other governments. There is need to better understand the implications of the policy decisions, the programs, and the activities of other governments.

A collaborative approach in co-ordination and conflict resolution between or among the three tiers of government should be developed. The relationship must not be confrontational and frigid. Regular meetings are necessary for timely resolution of any differences between or among the levels of government.

FUTURE RESEARCH DIRECTIONS

Inter-governmental fiscal transfers need well established formulas and formulas should be transparent based on credible factors. In this regard, there is need for further research. How do local governments below the provincial level deal with the challenges restructuring of responsibilities and powers between the different levels? What implications does this have for understanding decentralization in Zimbabwe? Other areas include nexus between devolution and intergovernmental relations; public finance management and devolution; and local participation in devolved areas.

CONCLUSION

This paper sought to... It has achieved.... It is concluded that,,

Devolution is not an event but a process that has distinct stages. Decentralization and devolution require a number of changes in administrative structure, allocation of functions and powers and control of resources. All three are interrelated and, to an extent, have to be introduced simultaneously. But it is almost a dictum of devolution that the changes should be effected gradually. Typically, it would be argued that the pre-conditions for successful decentralization and devolution have to be put in place sequentially and with a clear demarcation of functions among the various levels of government. Administrative support structures have to be created by effecting institutional changes, redeploying staff, generating linkages among various agencies and departments.

KEY TERMS AND DEFINITIONS

Decentralization: The diffusion of governmental authority and power away from the national center to other institutions at other levels of government or levels of administration

Devolution: The extensive form of decentralization that diffuses substantial governmental powers, authority, responsibilities, and resources to local units.

Local Government: System of government closest to the people.

Section Autonomy: The extent to which local governments have discretion in carrying out their duties and obligations.

Service Delivery: Socio-economic provision of goods and services such as roads, schools, and hospitals.

A Risk Management on Demographic Mobility of Evacuees in Disasters

Kazuhiko Shibuya

 <https://orcid.org/0000-0002-3243-4757>

ROIS, Japan

INTRODUCTION

To date, our global society is endlessly threatened by disasters (UNISDR, 2018). This article devotes to describe both risks and crises on disaster, and especially it deals with the nature of Fukushima case caused by accident of nuclear power plant (aftermath of the disaster at 11th Mar.2011). Since the human history, this case was one of extreme disasters and multiplied tragedies damaged by quakes, tsunamis, and nuclear power plant accidents. Still now, it presents a number of challenges indeed to be overcome. One of the hardest problems from the inventory of the Fukushima case was characterized as intensive purifications of nuclear pollutions around Fukushima and collective migration of evacuees caused by both natural and human-made disasters. And ongoing disputes against safety seem to vary widely such as compensations, socioeconomic reasons, environmental restorations and community reconstructions. The author intends to review these issues and discuss future design for the lessons from the disaster.

BACKGROUND

No blindness against the truth shall conceal the nature of the serious tragedies around the Fukushima. It should conquer an innermost meaning of sentence “*Ignoramus et ignorabimus*” (We do not know and will not know). Those who independently inquired into the matters ever since the crisis condemned collective optimism and anti-scientism among governmental authorities and polytechnics (Funabashi, Y&Kitazawa, K, 2012). They were hoping to stop more catastrophes, but they clung to saving their faces and dogmatic standpoints. Their statements against risks of nuclear power discredited any citizens. Consequently their poor management of risk prevention in nuclear energy following the tsunamis and nuclear power plant accidents magnified the damage. Their less attention has given to scientific verification ways (Cyranski, D, 2011). Through entirely investigations on consequences after the disaster, Japanese obtained the lessons: *no social systems exist without any scientific verification, and no solutions will be properly conducted without the efforts by true professionalism (academician, governors and other practitioners) involving civic engagements*.

In this point, the SCJ's report pointed out crucially lack of effective risk management for nuclear power plant accidents before the crisis (Science Council of Japan, 2011). Regarding this, in sociology of science, Merton, R.K (1968) already proposed his conceptual term ‘*CUDOS*’, namely *Communitas, Universality, Disinterestedness* and *Organized Skepticism*. Not to mention, scientific community in Japan should be recalled the significance of both Disinterestedness and Organized Skepticism in his prospective discussions. The rule of conduct among scientists as well as anti-crisis operations and imperatives by governors need to be critically reviewed whether national crisis or not. Eventually scientists must be

DOI: 10.4018/978-1-7998-3479-3.ch110

always devoting to strictly scientific governance in their community. Obviously, the social roles shall be undertaken by professional academicians and researchers in terms of their majors standing on the CU-DOS. It is too natural that they shall be obligated to solve above emerged and serious matters. Similarly JST (2011) proposed to solve and tackle those scientific matters by both social and natural scientists. For example, they enumerated modeling and simulation for disaster prevention, risk management, and risk communication for citizens as well as R&D on the nuclear power and new energy technologies (Sugiyama, et al, 2016).

FOCUS OF THE ARTICLE

Governance and Management at Disaster

When governors face at any extreme disaster (including anthropogenic, natural and combining one), they should eagerly devote to achievement of the future restorations (Curt,C.&Tacnet,J.2018). In this point, effective management including evidence based analysis and policy making should be quite needed for actual plans (Biello,D, 2012). Social media analysis also utilizes to unveil communication patterns during disaster (Li, et al, 2014). At least, these concurrent processes are required during disaster as follows.

- Ø *Demographic Data Management:* Migration and Evacuations, Total population of survivors, injuries, fatalities, and etc.
- Ø *Budget Management:* Financing for reconstruction assistances, and etc.
- Ø *Provisioning Management:* Relief supplies, Relief units, Allocating Temporary Evacuation Places, Necessary Resources, Medical cares, Information, Donations, and etc.
- Ø *Access Control Management:* Managing Traffic and Transportations, Restricting area against risks and hazards, and etc.
- Ø *Work Flow Management:* Coordinating total process control, Prioritization on evacuation plans and needs, Project management, and coordinating engagements among stakeholders and volunteers, and etc.

Regarding these points, governors should immediately, responsibly and comprehensively tackle necessary prioritizations. First, it should be tracking dynamics of evacuees and citizens' conditions. Secondly, it offers multiple transportations for evacuees and improves their mobility. Thirdly, it should prepare and allocate temporal housing for them. Of course, without saying, foods and water provision are quite necessary. However, according to revealed data after the disaster, many of municipal governments as well as the national government does not prepare efficiently evacuation plans for large migrants and evacuees. When magnitude 9 level disasters occur around the Tokyo capital area, some researches forecast serious shortages of necessities for two millions migrants and evacuees at least. Those conditions will further cause crisis such as transport congestions, collapse and others. Limitations of budgets and human resources will decisively call exhaustion and confusion in each city. Thus it should make a clearer orientation and plan against future disaster in each municipal city in advance (Batler, D, 2012).

After that, it should turn eyes to persevering purification from the radiation damage caused by the nuclear accidents, its environmental restoration, health monitoring and socioeconomic reconstruction in community (NRC, 2011; IAEA, 2011). As consequently, the Fukushima case definitely needs to solve

nuclear accidents and future design for long-term reconstruction on their devastated communities and hometown. At least, there are including following points.

- Ø *Decommissioning work for the wrecked nuclear power plants in Fukushima*
- Ø *Removal of nuclear fuel and substances*
- Ø *Chemical management on nuclear substances*
- Ø *Purifications in polluted places*
- Ø *Temporary storage and final disposal of contaminated soil, water, and garbage.*
- Ø *Medical health survey and care for victims*
- Ø *Risk assessment against environment and people exposed by nuclear substances*
- Ø *City and Socio-economic reconstructions*

Regarding this concern, enacted provisions often reflect social actualities. For conquests against those hardships of citizens and evacuees, the ‘*Basic Act on Reconstruction in response to the Great East Japan Earthquake (24th, June 2011)*’ enacted the basic policies for reconstructions. For example, a part of provisions clearly stipulated as following.

Article 2. The reconstruction in response to Great East Japan Earthquake will be implemented based on the following

- 1) The unprecedented disaster resulted in enormous damage, where countless lives were lost, numerous people were deprived of their basic living infrastructures and have been forced to evacuate in and out of the disaster-affected regions. Also, the disaster’s influence extends over the entire nation; the economic stagnation in the disaster-afflicted areas is affecting business activities and peoples’ lives nationwide...(hereafter omitted)

At the FY 2014, the total budget of Fukushima Prefecture for reconstruction after the disaster was approximately 1,714.5 billion yen (including both quakes and nuclear disaster countermeasure portion of 870.5 billion yen). And it also includes population declining and aging countermeasures as well as restoration of birth number (142.3 billion yen). In addition, there were 245.5 billion yen for environmental restorations, 144.3 billion yen for living reconstruction assistance, 36 billion yen for expenses to protect medical health of the citizens, 31.6 billion yen for expenses for children and youths who will be responsible for the future, and other expenses.

Further, in addition to above costs, the Fukushima case requires unprovoked compensations and its litigation disputes are ongoing matters in courts (Shibuya,K, 2017). Namely, there remains to solve future designing for reconstruction from devastation in their hometown.

After the disaster, in all things it is better to hope than to despair. But till now, it presents that a number of challenges indeed to be overcome. Nearly future, a decade after the disaster will pass. However both reminiscent verifications and proactive review are required yet (OECD, 2016; Sugiyama, et al, 2016).

With these regards, in this article, especially the author picks up and deliberates focal points as follows. The author formally defines a question. *How is the process of that demographic mobility after the disaster?* and *How to deal with compensation problems?*

1. *Demographic Dynamics after Disaster*
2. *Environmental Restorations and Compensation Principles*

SOLUTIONS AND RECOMMENDATIONS

Demographic Dynamics after Disaster

Principally, the Fukushima case displayed one of the hardest problems related to collective migration of evacuees from Fukushima prefecture caused by both natural and human-made disasters (Akabayashi, A. & Hayashi, Y., 2012). Whereas it is the very significant tasks to track evacuations of citizens at the emergency conditions, but there are often vulnerabilities to be missed. Especially, it should be shed light on forced migration and dynamics of mobility (Butler, D., 2011; Castles, 2003; Jacobse & Landau, 2003; Poston, D. L. & Micklin, M., 2005; Rogers, A., 2015).

At that time (11th Mar. 2011), national authority coercively restricted citizens to stay in wide polluted area around Fukushima nuclear power plants. Then many of ordinary citizens were inevitably destined to escape from Fukushima to other places. At the peak (May 2012), gross migrants from Fukushima (e.g. total population of evacuees) were estimated over 160,000. And including this, gross migrants (e.g. total evacuees in Japan) were estimated over 340,000 at the time of 2012. Of course, both Japan and its municipal governments were eagerly to announce safety information for residents around and nearby Fukushima nuclear plants. But stakeholders were critically accused by many evacuees and citizens, because they did not have any efficient controls and managements. Consequently it entailed severe distrust rooted in information-asymmetry between government and citizens, their risk cognition were imprinting in this way. In addition, this demographic estimation was not too low. Please recall similar cases, for example, the case of Chernobyl in 1986 reported that total population of evacuees was approximately 116,000 around 30 kilometers (INES level 7). And, in 1979, the case of the Three Mile Island accident was estimated over 240,000 around 24 kilometers (INES, level 5).

Ironically, casualties often reminded us a top priority to immediately grasp demographic dynamics after disaster. At that time, the USA government had immediately attempted to understand this tragedy in Japan. NRC (Nuclear Regulatory Commission) (2011) intensively tackled sequential causal analysis by their taskforce organized of nuclear professions. And Global Legal Research Center in the Library of Congress (2013) also already reported above Fukushima disasters and it pointed out the problems on tracking of evacuees and ordinary citizens.

In Japan, Ministry of Internal Affairs and Communications (MIC) and Reconstruction Agency mainly offered demography and disaster relative data¹. But it was unable to obtain data on demographic population and their households' conditions real-timely, and it was just discretely.

In year 2015, a national census every five years was carried in Japan, and it has achieved to unveil many data discrepancies and inconsistencies of population in each local area of Fukushima. Comparing with statistics on resident data holding municipal government office and actual population from census, the latter cases were almost too lower than expected populations in many cases of Fukushima. To date, these missing populations have been not tracing properly and many of evacuees did not intentionally apply immigration cards to municipal government office. It means that many of them still have strong wills to come back to Fukushima in the near future. However the stumbling blocks still remain against their returns, even though the government purifies radioactive substances and pollutions around their towns.

Table 1 shows a part of outflow data on migrants across cities (it includes mobility data within same city). It queried into big-data of MIC (e.g. demographic data of migration and population) and the Geo-spatial Information Authority of Japan (e.g. geospatial data and distance information). The numbers of citizens lived in Fukushima prefecture has been notably decreasing from 2.1 million (2011) to 1.9 million (2015). And this area is statistically 13,780 km² (the third widest area in Japan). And it compares

Table 1. Outflow Data on Mobility Across Cities in Japan (Compared with 2011 and 2015)(Data from Ministry of Internal Affairs and Communications, Japan)

		To								
		Fukushima		Tokyo Area		Nagoya Area		Osaka Area

Fukushima with people lived in major metropolis such as Tokyo area (total population is approximately 13 million people and within 9 million people in 23 special districts), Nagoya area (approximately 2.2 million people within central city) and Osaka area (approximately 2.6 million people within central city) in Japan. It namely denotes moving within Fukushima cities, moving towards one of metropolises from Fukushima and moving between metropolises.

Next, according to subsequent progress surveys in Tokyo capital city for evacuees (Shibuya,K, 2017), it found that their motivations which choose the destination and refuge were relying on critical factors: (1) to tie with any kindred relationships (a factor of human relationship), (2) opportunities of jobs in the new address (a factor of new job opportunity), and (3) conveniences to manage their own real estates, farms and factories in their hometown (a factor of holding estates). First factor implies mutual cooperation and helping among local acquaintances, and second answer clearly reflects their needs for job in new dwelling. And third factor relates to geospatial location. Many of citizens adhere to living around Fukushima, and then parts of them have been living in two places of both Fukushima and refuge. Namely, their conditions are back and forth between hometown and refuge. Thus they could not leave to far refuge, and geographical area around 300 kilometers within Fukushima and refuges satisfy their above motivations using transportations such as the bullet train, highways and other land transportations (it drives toward the destination within two hours). For those who required living needs, Tokyo and nearby area could properly offer new job opportunities and dwelling availabilities for them. Regarding this concern, Ravenstein,E.G.(1885) originally discovered ‘*The laws of migration*’, which depended on geospatial distance of collective immigrant workers between each city. Therefore, it is natural to think that this law explains demographic mobility patterns on the Fukushima case.

Environmental Restorations and Compensation Principles

Risk Cognition among Citizens against Pollutions and Contaminations

Nuclear pollution raised the disputes on human rights, health, radiation contaminations to foods and environmental restorations. Both environments (soil, waters and air) as well as people in Fukushima were polluted and exposed by both nuclear substance and radiation (Hayano,R.S et al, 2013; Gibney,E, 2015; Merz,M et al 2015; OECD, 2016). Sampling data accumulated by agricultural scientists endorsed that many of crops absorbed radioactive substances such as ⁹⁰Sr, ¹³⁴Cs, ¹³⁷Cs, and others (Nakanishi,T&Tanoi,K,

2013; Takahashi, T, 2016). And excessive intake and exposure of radioactive pollutants will also endanger citizens' and workers' health (Hiraoka, K, et al, 2015).

Thereafter, the anxiety of citizens against crops and foods was ascribed to above serious radioactive pollutants. Then, they were calling to refrain from purchasing foods and agricultural products made in Fukushima thorough any ways. This social phenomenon often calls severe controversies as a Japanese phrase “*Fuhyo-Higai*”. Of course, these safety matters were incurred temporally. To date, scientific investigations well assured of the safety of agricultural foods. For safety conservation, every crop has been required to pass the food safety examinations, and further the Fukushima prefecture managed the tracking of foods shipments from all Fukushima farmlands to buyers and consumers. But many consumers still uneasily claim skeptical sentiments. Certainly, it didn't subside notable stagnation in local economics. Thus, it is critically true that innocent and honest farmers lost their profits since that time. At least, this social trend was not only engendered by inaccuracy rumor and media communication. Rather, one of main factors was that risk cognition among citizens easily triggers the first domino-effect for disruptions in market and supply chains whether mediated rumor can be clarified or not. These cases indicated that many people did feel something unfavorable and they were not going to buy foods made in Fukushima. And food buyers almost broke the ties of trading and supply networks from suspected as well as trustable farmers, and supermarkets often expelled those agricultural foods (it just labeled and categorized as “Made in Fukushima”).

Externality and its Compensations

With these backgrounds, the focal point of disputes on the compensations has been accused by plaintiff (i.e. citizens, evacuees, and victims) under trials in courts (OECD, 2016). In the Fukushima case, many trials as class action lawsuits are ongoing matters, and these judgments of the first instances are all favorable by the plaintiff. The points of dispute can be summarized as follows. (1) *compensation for health damage to evacuees*, (2) *a situation in which citizens have to evacuate for a long time*, (3) *collapse of the community*, (4) *restoration of the state of origin*, and (5) *execution suspension of the exercise of regulatory by defendants (i.e. National Government and Tokyo Electric Power Co., Inc.)*. Naturally their legal battles may continue, but law courts will almost uphold plaintiff. Further total amount of those compensations can be easily expected to exponentially rise up. And then, with reducing the burden against the gross domestic product in Japan, it is quite important to recover the sales networking, restore the productive capacity of the afflicted area, address the economic damage of producers and make efforts for future economic development. At the time of 16th October 2013, the Board of Audit of Japan estimated the total burden against the compensations in the Fukushima nuclear power plant, and its amount will exceed five trillion yen and more. Additionally, they also simulated that it will take more 31 years to repay the full amount.

Furthermore, it should be also pursued these matters including environmental goods (i.e. non-market goods), its assessment and value restoration. As the first step, there are needs to formal assessments and estimate economic utility of environment itself. Please recall the US NOAA Report (1993), it is indispensable to find the policy problem by evaluation on environment itself and to explore the steps for improvement. Here, before the disaster at 2001, Fukushima Prefecture had already estimated their utility valuations holding environmental real estates (e.g. forests, mountains, rivers, etc.) by travel cost methods as one of revealed preferences methods. According to them, they estimated total value of both ‘flood prevention function’ and ‘air purification function’ was about 286 billion yen. In the breakdown, the value of 55.2 billion yen was calculated for ‘health rest and relief function’. From this point of view,

anyone can clarify the transition of value before and after the disaster (Not to mention, *at least* they lost those values by the disaster).

In the first place, if the damage occurred on the basis of the economic activity of the company, its actual damage called '*negative externalities*' in economics. If the damage was caused by a kind of anthropogenic disasters, the criminal liability is socially relying on the economic activity of the enterprise, which is a result of having a negative effect on the citizens living in the area where the disaster occurred. Certainly, it is often very difficult to coordinate with social welfare functions among stakeholders (Arrow, 1963; Sen, 1970). As well-known as 'Kaldor-Hicks compensation principle' (Hicks, 1939; Kaldor, 1939), it has been discussed in the field of welfare economics, it was damaged due to the externalities by corporate economic activities, and the focal point is on how they compensate for their victims. However, when each preference between the company and the victim can be defined, it has been proofed that their social choice in society does not necessarily reach to the Pareto optimum. As for this problem, Sen (1970) strictly deliberated that the Kaldor-Hicks compensation principle prevails in the process leading to the social choice based on preference order is limited, and the defect was resolved by the new compensation principle by Scitovsky (but Skitovsky's proof had also been shown to have drawbacks, which has been critically revised by Sen). Meanwhile, in Fukushima cases, many of lawsuits said that compensation amounts are unequal conditions among victims. Economically speaking, so far, Sen also asserts that the assessment of inequality in economics has been neglected in economics, and he taken up as an example of social loss due to Atkinson's equivalent income. As taking into account the diversity of individuals, he definitely defines inequality.

Regarding this context, the Coase theorem (Coase, R.H, 1960) defines to fulfill three conditions such as (1) *low negotiation costs*, (2) *clarity of attribution of rights*, and (3) *endorsement for completeness of information*. However, there is no guarantee that nuclear accidents will satisfy these conditions. In particular, the completeness of information is not guaranteed in the Fukushima case. Moreover, regarding negotiation and transaction costs, risk assessment and safety inspection expenses will increase according to the damage. In addition, the impact of secondary damage, the disappearance of regional brands as 'public goods' and the repair costs will not necessarily be ruled in this theorem. As high level expertise in engineering and related fields is required, information asymmetry among stakeholders can not still fill in the gap between them. For these reasons, the actual solution will not be easy as the theorem assumes.

FUTURE RESEARCH DIRECTIONS

All things considered, the Fukushima case impressively implied us the significance of maintaining habitable zones and environmental restorations damaged by nuclear accidents. Development of human's civilization was coeval with an inevitable and strong problem on interlinks between population and geospatial environment (DeMenocal,P.B&Stringer,C, 2016). Loss of control will be a menace to our sustainable society. In the context of the four priorities for actions based on the Sendai Framework for disaster reductions, it is certainly that various methodologies and in-depth ideas were quite needed. Especially, simulation methodology offers the benefits for stakeholders (Meadows, D.H et al, 2004; Shibuya,K, 2004, 2017). It could demonstrate some base scenarios using various environmental, socio-economic and demographic factors. As integrating with systematic concerns, it is possible to simulate the interlinked problems. The further studies should unveil multiple influences between causes and results for resilience of communities and socioeconomic reconstruction.

First, many citizens lost their tolerance of unsafety when governors trampled on their daily lives, and then they left Fukushima. Restoration of the natural environment due to radioactive contamination was a serious problem in itself. As stated by outside stakeholders, pollution on agricultural crops became noticeable. So even if some residents returned home and the community was physically rebuilt, as long as agriculture is the core of the regional economy, their reconstructions will be still difficult. In fact, there are many citizens who settled in evacuation outside the prefecture, and gave up the return.

Secondly, for next several decades, it should assess some scenarios based on the time discount principle in Fukushima. Can stabilize economic valuations between contemporary and future generations? As long-term reconstructions, any present value does not have equal value in the future. There are the necessities to examine detail dynamics and linkages in socioeconomic and demographic factors. Through intensive investigations, it will unveil multiple influence factors against disaster resilience and socioeconomic reconstruction. For instance, when temporal migrants and evacuees finally become long-term residents and settlers in city, each city should reconsider socioeconomic balances for acceptance of migrations. It is similar to the migration policy studies in economics (Powell, B., 2015). Increasing active workers' population raises economic benefits for accepting city, but retired generations require their pensions and social welfare services.

Thus for future generations in Fukushima, the basic design on these matters should not be reshaped by a standpoint of contemporary generations. It remains to solve the problems including a perspective of the future generations. Their consensus should be depended on future plan (Johnson, G.F., 2008). It prioritizes more future common wealth than present value based on individual's preferences. However, it will be perhaps the long way to achieve their goals.

CONCLUSION

The goal of this article was to review the nature of the Fukushima disaster. The author deems the necessary to further contemplate those matters for risk and crisis management. This case presents a number of challenges still to be overcome. And it should be deepened by future studies for envisioning the sound design in regional communities.

KEY TERMS AND DEFINITIONS

Coase Theorem: Coase theorized economic balance between efficiency and outcome caused by externalities among stakeholders in economics (Coase, 1960), and it defines to fulfill three conditions such as (1) low negotiation costs, (2) clarity of attribution of rights, and (3) endorsement for completeness of information.

Kaldor-Hicks Criterion: This criterion refers to discussions on compensation principle in welfare economics (Hicks, 1939; Kaldor, 1939), and it also widely applied in policy studies and environmental studies. It characterizes the form of cost–benefit analysis. In the cost–benefit analysis, each policy is deliberated and evaluated by comparing the total costs (e.g., building costs and environmental costs) with the total benefits (e.g., profits and convenience for stakeholders).

Migration and Evacuation in Disaster: Aftermath of the serious disasters, it should be shed light on migration and demographic dynamics of evacuees. Certainly, it should distinguish between forced migration and spontaneous one (Castles, 2003; Jacobse & Landau, 2003). Formally, the former can be considered that governors and officers in charge can enact necessary legal imperatives for citizens, and the latter can be based on the will of each citizen. However, human-made disaster usually generates inevitable matters against unneglectable risks, and then every stakeholder directly faces the evacuation problems.

GIS–Based Quantitative Landslide Risk Assessment Approach for Property and Life at Bartın Hepler

Arzu Erener

Kocaeli University, Turkey

Gülcan Sarp

Süleyman Demirel University, Turkey

Şebnem Düzgün

Colorado School of Mines, USA

INTRODUCTION

Landslides are the second most common natural disasters that cause damages in Turkey after the earthquakes (Ergunay et al., 2003). 89% of the middle and the eastern parts of the Black Sea Region are reported to be susceptible to landslides (Toprak Su 1978; Öztürk 2002). Thus, landslide risk assessment is of crucial importance in decreasing the potential losses.

However, attempts to determine qualitative and/or quantitative risk assessment seems to be fewer (e.g. Wang and Unwin 1992; Fell 1994; Chung et al. 1995; Carrara et al. 1995; Jibson et al. 1998; Aleotti and Chowdhury 1999; Chung and Fabbri 1999; Chowdhury and Flentje 2002; Dai et al. 2002; Bell and Glade 2004; Remondo et al. 2008; Erener and Düzgün 2010; Silva and Pereira, 2014; Luna et al., 2014; Erener, et al., 2016, Erener et al. 2017; Pereira et al., 2017; Vega and Hidalgo, 2017; Hidalgo et al., 2018; Vega et al., 2019) which might be due to the difficulties in obtaining data.

One of the chief advantages of a Quantitative Risk Assessment (QRA) is that it can be compared with other types of risk that can affect a community and since of its quantitative nature it can be communicated more comprehensible to the policy and decision-makers to be used for risk management policies (Luna, et al., 2014). In recent years, Geographical Information Systems (GISs) and Remote Sensing (RS) have proven to be common tools adopted for various studies. In this study, a GIS-aided quantitative landslide risk assessment approach is proposed with an application to local-scale.

BACKGROUND

Quantitative Risk Assessment (QRA) requires quantification of losses due to a given landslide hazard. When landslide hazards are investigated in a local scale, it is necessary to predict the run-out area to identify the potential damages to elements at risk. In any QRA it is of fundamental importance to identify and characterize elements at risk (e.g. buildings, roads, utilities, lifelines) for predicting losses. If insufficient or no digital data exist on a local scale, remote sensing products can be used to extract the element at risks, such as road networks and buildings. Most of the works in the literature concentrates only on the extraction of a single object such as only buildings or only roads. Typical examples of early

DOI: 10.4018/978-1-7998-3479-3.ch111

works in building detection are Lin and Nevatia (1998), Kim and Nevatia (1999), Peng and Jin (2007), Vakalopoulou et al. (2015). On the other hand, Klang (1998), Laptev et al. (2000), Amini et al. (2002), Mena and Malpica (2003) Christophe and Inglada (2007), Yang and Wang (2007), Aytekin et al. (2012) used the most common algorithms for the detection of road.

The population data is required for each individual building to estimate the loss of life due to landslides for risk assessment studies. The population data can be collected through surveys that are time-consuming and costly. On the other hand, recently RS has proved to have the potential for predicting the population with low cost and up-to-date data. Zhang (2003), Lu et al. (2006), Morton and Yuan (2008), and Erener and Düzgün, (2009) has examined residential population dynamics from satellite remote sensing images.

Vulnerability is another fundamental component in QRA (Leone et al., 1996). Reviews of landslide vulnerability are made by Glade (2003) and Lee and Jones (2004). The vulnerability of static elements at risk, such as buildings, land-use, roads, etc. does not vary with time. They are always exposed to threats for all time in all day or all year. On the other hand, the vulnerability of dynamic elements at risk may change depending on their geographical and temporal existence with respect to landslides and it is more difficult to estimate the vulnerability for these elements. Thus, for dynamic elements (residents of the buildings, cars, trains, etc.) daily and seasonal movements are also required for a reliable estimation. Quantification of elements at risk requires a compilation of data from different organizations through interviews with the employees, which is a time-consuming process. Therefore, the assessments of vulnerability for landslides in the literature are usually qualitative (Rautela and Lakhera, 2000) and mostly depend on historical records (Dai et al., 2002; Glade, 2003). For effective use of QRA, generalized quantitative models for vulnerability assessment are essential. Several procedures are described in the literature for the assessment of vulnerability, (e.g. Mejia-Navarro et al. 1994; Fell 1994; Leone et al. 1996; Glade 2003; Uzielli et al. 2006).

FOCUS OF THE ARTICLE

This study introduces a GIS based approach for QRA and illustrates its implementation to Hepler village in Bartın Province, Turkey. GIS is very modern and useful data entry, processing, analysis, query and update tool for both spatial and attributes data (URL1) used at whole parts of this study. On the other hand, RS is an effective data collection method for GIS. A generic algorithm (Aytekin, et al. 2012) that consider road and building extraction together from remote sensing images is adopted in this study for detection of elements at risk. Landslide run-out models being used for assessing the vulnerability values quantitatively on local scale. The velocity of landslide in its run-out area and the number of inhabitants per house are taken into account to quantify the vulnerability related to the elements at risk at GIS environment. In contrast to the property, human exposure to the landslide occurrence may vary depending on the temporal impact. Therefore, the temporal impact is considered for the residents living in buildings. In this context, the occupancy of buildings by people at different times is considered in the study. Hence, the vulnerability of human life is evaluated for temporal scales of day time, night time, high season time, and low season time. Furthermore, the vulnerability of buildings and road are estimated by adopting the damage probability matrix approach by Düzgün (2008). This approach is used in earthquake engineering for evaluating the damage of building stock for a given earthquake intensity (Ko Ko et al., 2004).

As a result of the analysis, quantitative risk maps for both life and property were obtained by the evaluation of hazard, vulnerability and consequence maps for each element at risk at GIS environment. A combined landslide risk map was obtained by adding risk for each element at risk on a continuous

Figure 1. Location map of the study region

scale where numerical values indicate the distribution of risk including the annual probability of expected losses in \$ per pixel and the annual probability of life loss per pixel for property and life, respectively.

METHOD OF STUDY

Hepler is a small village located on a hillside. It exhibits mountainous topographical features and is frequently subjected to heavy precipitation. Due to these adverse effects, the village is prone to extensive and severe landslides. There are approximately 45 buildings, many of which are constructed on the slope with one and two stories. The population in Hepler village is approximately 250, which may change during summer or winter. The village covers 0.5 km² and is located approximately 8 km southwest of Kumluca town. The 3D view of the study region is given in Figure 1.

The topographical elevation varies from 241 to 527 m above sea level. The predominant slope angle is approximately 24° with slope angles ranging from 0° to 65°. Depending on the reports of the General Directorates of Disaster Affairs of Bartın, the settlement is on an old landslide mass. Landslide mass is identified in lithologic units of Upper Cretaceous age Flysch, which is named as the Uluş formation. The Flysch formation is comprised mostly of thick sandstones in the lower parts, then sandy, clay schist, clay marl, and claystone units on the upper parts. The average soil thickness varies between 30 and 40 cm. The Flysch formation is saturated due to extreme snowmelt in the winter and rainy season in the spring. It is reported that it rains above average during seasonal rains and it snows more than 1.5 m high. The snow melts slowly and as a result, the terrain covered with clay absorbs the whole water. As the terrain becomes saturated with water, landslide and mudflows occur.

In order to determine a detailed topography of the slope and assess the properties of the landslide, extensive fieldwork was carried out. The Ashtech Kinematic GPS (Global Positioning System) was used to collect the X, Y, and Z coordinates of the surface topography with an accuracy of ± 0.5 m (at 95% confidence interval). When terrain conditions were not suitable to collect data points with GPS because of the dense vegetation cover or steep slopes, TruPulse 200 Laser Range Finder was used. The measurement range of the range finder is up to 3280 ft (1000 m) in distance and ± 90 degrees as inclination. It has an accuracy of ± 1 ft (± 30 cm) in distance and ± 0.25 degrees as inclination. The data points were collected homogeneously from the whole slope and as a result, the DEM was constructed at 1 m

Figure 2. The cracks and scarps observed and mapped through field survey at 6-7 June 2009 and the photos of the terrain with scarps and crowns

grid size, using a Triangular Irregular Network (TIN) approach. The observed cracks and scarps through the field survey were mapped onto the remote sensing image of the study region (Fig. 2).

As presented in Fig. 2, in the southern part of the region, transverse cracks were observed. Moreover, the main scarp boundary and crowns were observed at the top of the slope. Some of these cracks are shown in photos given in Fig. 2 a, b, c and d. The crowns observed through the study region were mostly 30-40 cm deep. Depending on the interviews with the local people, these artifacts occurred between 2008 and 2009. Thus, these fractures indicate that the slope mass is still active and slowly moving.

Consequence Analysis

On a local scale, run-out area is critical in identifying the elements at risk and associated vulnerabilities to analyze the consequences of a landslide. A physical process model (Flo 2D) was used for modeling the run-out. Flo 2D is a two-dimensional finite-difference model that simulates clear water, flood hazards, mudflows, and debris flows. The objective of this model is to estimate the probable range of flow properties in terms of velocity and depth to predict a reasonable area of inundation O'Brein et al. (1993) and O'Brein (1999). The details of the modeling the run-out was presented at (Erener, 2009). The model provides the velocity of the debris flow so that the vulnerability of the buildings and also the vulnerability of the people living in the buildings could be predicted depending on their exposure to slide velocity. The velocity map of the simulated slide changes with the volume concentration and ranges between 0.01 and 1.55 m/s. The spatial variation of velocity values over the study region and the distribution of houses are illustrated in Fig. 3.

The distribution of the elements at risk in space and time was extracted from the Quickbird image for the consequence analysis. The details of the image analysis algorithm were presented at Aytakin et al. (2012). The elements at risk in the considered region mainly involve buildings, roads, and populations. Fig. 4 shows the delineated candidate buildings detected for each sub-region with the proposed algorithm and overlaid over the manually labeled ground truth.

Road objects are significant infrastructures for risk analysis. Thus, the roads were also considered in the study for the vulnerability analysis and extracted automatically by the developed algorithm from the

Figure 3. The velocity map of the simulation result (m/s)

high resolution remote sensing image (Fig. 5). The elements at risk obtained from the Matlab environment were then assigned to GIS environment for further risk analysis.

Vulnerability Assessment

The degree of damage in buildings and road, (vulnerability) can be estimated by adopting a damage probability matrix (Yüçemen, 2002; Düzgün, 2008). This approach was used in earthquake engineering for evaluating the damage for a given building stock at a given earthquake intensity (Ko Ko et al., 2004). In this approach, instead of building blocks, the buildings and the road were considered separately by the damage probability matrix. Damage to buildings and the road was categorized into four groups based on the degree of damage. Damage State (DS) was considered in four levels, changing from none to destruction, in which none and destruction stand for no and complete damage. The Range of Damage

Figure 4. The candidate buildings extracted at the end of the algorithm overlaid on the ground truth

Figure 5. The road detection outputs in the sequence where 1: The vegetation and shadow mask; green is the vegetation and shadow mask, red is the man-made features (road and buildings) 2: The resulting map obtained from the linear feature detection algorithm. 3: The resulting map after PCA algorithm. 4: The resulting map of both linear feature detection and PCA is overlaid to obtain the road feature 5: The morphological processes (imfill open, erode, close) implemented to road feature 6: The road feature overlaid to the remote sensing image

Ratio (RDR) for each damage percentage is defined as 0, 0-10, 20-40 and 50-100 (Düzgün, 2008). Central Damage Ratio (CDR) is defined as the mean value of RDR. The probability of damage state (SPD) for the given temporal condition (season in a year and time in a day) is determined. The properties (such as buildings, roads, etc.) are always exposed to threats all the time. Hence the temporal probability is not considered for the vulnerability analysis of properties. SPD is computed by considering the spatial vulnerability of buildings, which is determined by modeling the landslide velocity using Flo 2D. In the first step the velocity was normalized to 0 and 1. In the second step, the velocity map was classified into four different classes depending on the natural break method. Finally, the percentage area of each property on each level of landslide velocity was computed by the overlay of the velocity map with buildings and roads, respectively. The SPD is the percentage ratio of each feature computed for buildings and roads on each velocity level (Table 1).

Table 1. Damage Probability Matrix for Buildings and Roads

Damage Probability Matrix for Building				Damage Probability Matrix for Roads		
DS	RDR (%)	CDR (%)	SPD	RDR (%)	CDR (%)	SDP
None	0	0	0.2	0	0	0.71
Light	0-10	0.05	0.5	0-10	0.05	0.11
Moderate	20-40	0.3	0.1	20-40	0.3	0.19
Destruction	50-100	0.75	0.1	50-100	0.75	0
Mdr (%)			15			6.08

The MDR is computed for each damage state by sum of the multiplication of CDR and SPD values as presented in Eq. 1

$$MDR = \sum_{j=1}^4 CDR_j \times SPD_j \quad (1)$$

Where j is the level of damage state that ranges between 1 and 4, in which 1=None, 2=Light, 3=Moderate, and 4= Destruction

The damage probability matrix was created by considering the occupancy of people in the building. In contrast to the property, human exposure to the landslide occurrence may vary depending on the temporal impact. The day and night and also the summer and winter should be considered for the assessment of consequences. Hence, depending on the interviews with the local people, the occupancy of each building is found to be between 3 and 10 for low and high seasons, respectively. Seven months of a year (October, November, December, January, February, March, April) were considered as the low season (LS) and the other five months were considered as the high season (HS) (Düzgün, 2008). The probability of landslide occurrences in low (PLS) and high seasons (PHS) was then computed as 0.58 (7/12) and 0.42 (5/12), respectively.

In addition to the time component, the spatial vulnerability of each building should also be considered. Depending on the simulated velocity of landslide, the vulnerability of each building was determined.

Depending on the simulated landslide velocities and the survey data, a quantitative SPD was defined. SPD values are consistent with each other, where MDR for HSNT has the highest value, while MDR

for LSDT has the lowest one (Table 2). Damage state (DS) was considered in three levels which involve none, injury, and fatal. The range of damage ratio (RDR) for each damage percentage was defined as 0, 10-80 and 80-100 by adopting the assumption of Düzgün, (2008).

Table 2. Damage Probability Matrix for Loss of Life

DS	RDR (%)	CDR (%)	HSDT	HSNT	LSDT	LSNT
None	0	0.00	0.44	0.22	0.41	0.34
Injury	10-80	45.00	0.53	0.27	0.49	0.41
Fatality	80-100	90.00	0.10	0.51	0.03	0.25
Mdr (%)			32.87	57.64	24.74	40.95

SOLUTIONS AND RECOMMENDATIONS

Risk Assessment

Risk assessment consists of integrating loss analysis with hazard analysis. Landslide hazard analysis requires determining the spatial and temporal probability of occurrence of damaging events (Bell and Glade, 2004). The hazard maps created for Kumluca basin described in detail by Erener and Düzgün (2012) were used to obtain the hazard values for Hepler village. The area for the Hepler village in the regional hazard map was selected to identify the local risk (Fig.6a).

After the determination of the hazard values from the regional scale hazard map, the risk was estimated for Hepler in the GIS environment. The risk to property was obtained for Hepler by considering the roads and buildings on local scale. The cost of buildings, which is determined by the General Directorate of Disaster Affairs of Bartın, was used to assign the economic value, which is 18.15\$/Pixel. The cost of roads was obtained from the General Directorate of Transportation for the provincial type, which is 751,100 for one km and computed as 11.55\$/Pixel.

The risk was computed for each property (building and road) separately. Then the total risk map was obtained by overlaying all risk maps. The risk computation involves the multiplication of each property value with MDR values and then multiplication by hazard value.

$$\text{Risk}_{\text{Prop}} = R_{\text{Building}} + R_{\text{Road}} \quad (2)$$

$$\text{Risk}_{\text{Prop}} = H \times (\text{MDR}_{\text{Building}} \times 18.15\$/\text{Pixel}) + H \times (\text{MDR}_{\text{Road}} \times 11.55\$/\text{Pixel}).$$

As a result, for the assumed damage probability matrix in Table 3, the annual risk to Hepler was estimated for TL/pixel cost of damage for grid and slope-unit based mapping units and for different mapping methods. Fig.6b illustrates the spatial variation of risk values for risk to the property.

The risk of loss of life can be computed by the sum of the multiplication of H and MDR values for damage states for loss of life as given in Eq (3):

$$R_{\text{LOL}} = H \left[P_{\text{HS}} \left(\text{MDR}_{\text{HSDT}} + \text{MDR}_{\text{HSNT}} \right) + P_{\text{LS}} \left(\text{MDR}_{\text{LSDT}} + \text{MDR}_{\text{LSNT}} \right) \right] \quad (3)$$

Figure 6. The grid-based LR hazard map levels for Hepler district (a); Risk to property (\$/Pixel) Max value: 54.053 (\$/Pixel), Min Value: 3.22 (\$/Pixel) (b); Risk of loss of life (Loss of Life/Pixel) (c)

As a result, the annual risk maps for loss of life were estimated, which is illustrated in Fig.6c.

FUTURE RESEARCH DIRECTIONS

Landslide risk assessment is still in its developing stage, and most countries do not have a standardized landslide risk assessment process. In Turkey, there are a few studies for risk mapping for landslides. Therefore, this study contributes to the literature by designing a loss estimation approach for quantitative risk assessment.

The developed algorithm to obtain features from high-resolution RS images provides an automatic way for obtaining elements at risk features. The cost of these images is comparatively lower for a small region than field observations when considering transportation and individual expenses in addition to

expenses for equipment. However, for future work, this algorithm can be improved to reduce errors by adapting new image processing methods suitable for rural areas. The use of the velocity value of run-out is new for vulnerability assessment and several issues such as rheology computation and model calibration are needed to be incorporated into the analysis. In addition to temporal impact, which is considered in the vulnerability approach, the probability of being in run-out zone for elements at risk, the construction type, the replacement cost of particular buildings, etc. may also be considered for further vulnerability assessment studies.

CONCLUSION AND DISCUSSION

The risk maps were obtained by the evaluation of hazard and consequence maps for each element at risk. A combined landslide risk map was obtained by adding risk for each element at risk. As a result, quantitative risk maps were produced on a continuous scale where numerical values indicate the distribution of risk including the annual probability of expected losses in \$ per pixel and the annual probability of life loss per pixel for property and life, respectively. The risk maps for loss of property provide a low risk value for the road; however, the risk values vary for building and provide medium and high levels of risk for buildings. Similar to loss of life, the buildings at the northern part exhibits higher risk values compared to the southern part of the region which might be due to the physical properties of the terrain which is related to the slope angle.

There is not a common method of vulnerability assessment in landslide risk mapping. The vulnerability approach designed for this study is based on the damage probability matrix and run-out velocity, which is novel to assess the vulnerability values quantitatively.

Consequence analysis, which involves elements at risk and vulnerability, is crucial for risk mapping. The elements at risk and vulnerability values depend very much on the scale of the investigation. Thus, the changes in consequence at different scales should be considered to assess changes in the resultant maps. The performance of risk mapping is strongly dependent on data constraints and financial supports. Additionally, each component of the risk assessment procedure requires the incorporation of data from diverse disciplines due to its multidisciplinary structure.

Therefore, the quality, reliability, completeness, and resolution of data should be considered prior to analysis.

The result of the analysis indicates that GIS and RS are very efficient technologies to handle, analyze, evaluate and overlay several data layers relevant to risk analysis. These maps are useful to evaluate the landslide risk of a region and it provides disaster mitigation benefits to housing and infrastructure. By using these maps, decision-makers can develop risk mitigation strategies and perform cost-benefit analyses for future land use planning.

KEY TERMS AND DEFINITIONS

Element at Risk: Features under risk including buildings, roads, land use, and infrastructure.

GIS: Geographic information systems is a technology that is used to capture, store, manipulate, analyze, manage, and present spatial data.

Landslide Hazard: Information about probability of occurrence of a landslide in a given area over a specified period of time.

Landslide Risk Assessment: Establishing the likelihood to which future slides could adversely impact society.

RS: Remote sensing is the acquisition of information from earth without making physical contact with the object by using satellite- or aircraft-based sensor technologies.

Vulnerability: Defined as degree of loss, suffer harm for a given element or set of elements within the area of hazard event.

INTRODUCTION

The television series *The Walking Dead* has reached more than seven million “likes” on Facebook and more than 300.000 in Twitter through March of 2012 (March, 2012), which lead very well scholars to think that the popular culture has widely adopted the figure of Zombie as a new genre of entertainment. The idea of the “Undead” not only coincides with the contemporary needs of morbid consumption (gaze) but also with the rise of new capitalism that commoditizes “the other’s death as a vehicle towards the individual emancipation (Korstanje 2012). The undead, broadly speaking, inhabit and proliferate in this earth while they are undesired by the human civilization. They were like us, but today they are death!. The Walking dead appeals to a climate of total destruction which often does not resonate with a form of public consciousness, but in the collective unconsciousness. The undead represents a postmodern sensibility. This sensibility reeks of decay.

“[It is a] ‘degraded’ landscape of schlock and kitsch, of TV series and Readers’ Digest culture, of advertising and motels, of the late show and the grade-B Hollywood film, of so-called para literature with its airport paperback categories of the gothic and the romance, the popular biography, the murder mystery and science-fiction or fantasy novel: materials they no longer simply ‘quote’, as a Joyce or a Mahler might have done, but incorporate into their very substance”. (Jameson 1991:55)

As the previous backdrop, Jameson argues that the postmodern culture rests on representations revolving around the “unconscious”, in which case, it articulates a specific discourse that interrogates in the political sphere. In a similar vein, the arts have represented, in what might be considered prescient ways, what has already begun in the economic, political, and social structures, but has not yet appeared in explicit terms. Somewhat arbitrarily stated, modernism began in the mid-nineteenth century. Charles Baudelaire called it *modernité*.

As Ulrich Beck puts it, the obsession of modern man to control the nature opened the doors to the idea that the same technology used by making of this world a better and safer place, can usher mankind into a nuclear apocalypse. One of the paradoxes of modernity began but it was not limited to the Chernobyl Accident. Technology played a leading role in the configuration of a Cold War, where the US and the Soviet Union devoted their resources to an incredible arms race. Beck acknowledges that at the time some risks are successfully mitigated by the action of technology and rational technique, new ones emerge. What is more important, the state of disaster results from the excess of modernity (Beck 1992). Jacques Ellul interrogated philosophically on the negative effects of technology in modern society, not only undermining critical thinking but also controlling -if not commoditizing- other lay-citizens (Ellul 1962; 1992). Andrew Feenberg calls the attention on technology, a-la-Marcuse, as a form of new rationalization, which means control over the rank-and-file worker. Technology disposes not only from bodies

DOI: 10.4018/978-1-7998-3479-3.ch112

to enhance the means of production but tries to domesticate nature through the capitalist wage system. While machine operates to make our lives safer, the western rationality imposes over other voices and cosmologies (Feenberg, 1995).

In the present chapter, we interrogate not only on the nature of technology but its connection with the bottom days theory and the Zombie world. After reviewing plots as *The Matrix*, *Noah and the night of the Living Dead* (among others), we hold the thesis that technology gives humans the opportunity to emancipate themselves from their limited condition, but at the same time, it may be very well a potential oppressor when ethics is derided. The chapter is not intended originally to managers and policymakers, simply because I am a social scientist. However, top-managers can enrich their diagnosis of organizational issues after reading it. Another limitation of the work consists in its lack of empirical evidence. Whatever the case may be, it provides fresh anthropological insight about the role of technology in the social imagination, to be more exact in the archetype of the bottom days. From the immemorial times, technology prompted the rise of empires and great civilizations while the precondition for a climate of extreme violence or war that accelerated the decline of society. The question whether the sin, greed, and omnipotence ushered mankind into the ruin was widely discussed within historians. This chapter explores the theory of apocalypse as a precondition where humans are not destroyed but purged towards a new *rebirth*.

Background Section

Every culture has tales about an exemplary center, an immemorial life where human beings and god coexisted in harmony. This paradise, a term coined by Eastern religions, has prevented access by humans the founding parents committed a crime, sin or other norm violation. From that day on, civilizations try to regain the primitive state of nature where suffering did not take place (Cohn 1996; McGinn 1996; Kumar 1996). One of the intriguing aspects that characterize the end of the World associates to what Eric Ranking dubbed as “the introduction of dark technology”. To put this in other terms, he holds the thesis that the world, no matter the tale, will never be destroyed but it is only reconstructed by the articulation of a purge. Humans not only offended the Gods following their greed but also are a real threat to the natural order. Gods conduct a purge to correct this “original sin” while the earth is redeemed into a new sanitized facet of existence. In these terms, as Rabkin explains, the exile represents the human impossibility to return to the exemplary center, but what is more important, it reminds the world may be destroyed because of human greed (Rabkin 1986). When the world is destroyed, what humans do not disappear, but they are forced to live in a new condition. In consonance with Rabkin, Gary Wolfe uses the term *Zero Moment* to refer the return to a primitive state where humans struggled for surviving. Once the world is destroyed, simply the hierarchal authorities are withered away, as well as all constitutional rights. While a new aristocracy arises, the state of prosperity or well-being earlier the moment of Armageddon never comes back. Technology paves the ways for the emergence of self-contained empires, while gradually when it is instrumentalized to protect the interests of a ruling elite, corruption marks the beginning of the end of the human race. The term, *remaking zero* crystalizes the efforts of humans to understand their being in this world. The civilization is born and dies thanks to technology, reminding that.

“The promise inherent in the idea of remaking zero is certainly one of the reasons this genre has survived as long as it has, and in so many guises. On the simple level of narrative action, the prospect of a depopulated world in which humanity is reduced to a more elemental struggle with nature provides a

convenient arena for the sort of heroic action that is constrained in the corporate, technological world that we know” (Wolfe, 4).

In this respect, *The Matrix* offers a good explanation that ascertains how and why technology is a key-player of human decline. Let's firstly clarify this Saga, which was starred by Keanu Reeves, Carrie-Anne Moss and Laurence Fishburne narrate the grim days of humanity which is exploited by Machines. Needless to say, the plot situates us in a futurist world, where humans have been enslaved by “the Matrix”, a great computer dotted of artificial intelligence. The Matrix -though created to serve humans- changes its orders subduing them into a fictional (simulated) reality. In the simulation, people are free to travel, work and live a normal life, but they are connected to a pod that provides to the Matrix of the necessary electrical activity the body offers. A young computer programmer (Thomas Anderson), Neo discovers that he was living in a simulation. He believes something is not working fine but continues without knowing he will be part of something great. Anderson is met by Trinity (Moss), a hacker who introduces Morpheus (Fishburne) to Neo, who is invited to make a difficult decision. On his hands, there are two pills. The red pill offers a revelation but leading Neo towards a hostile (but real) world. Rather, the blue pill leaves things as they stand ushering Neo into a comfortable but routinized world. Neo swallows the red option disintegrating him and appearing naked in a liquid-filled pod where he is rescued by Trinity and Morpheus. The plot is that in the 21st-century machines are empowered by humans to embrace artificial intelligence. In a rebellion, these smart machines confront humanity in a bloody war. At the time, the sun was blocked to prevent their advances so the machines cultivated human bodies as valid sources of energy, as a harvest disposed to extract bioelectricity. In one of its adventures, Neo and his friends enter the Oracle who prophesized that Neo is the One, a type of chosen messiah that will liberate humans from the machine's yoke. Morpheus and Trinity are betrayed by Cypher a crew member who renounces to the sense of reality for the wonderland offered by the matrix. Cypher negotiates with Agent Smith in exchange for having a comfortable life. Cypher disconnected some of the crew members while they were in the matrix which meant certain death, but failed in doing the same for Trinity and Morpheus. Cypher is killed by Tank. Morpheus is interrogated to know the exact location of Zion, the last rebel base under the earth. Trinity and Neo help Morpheus in escaping from Smith's traps. Here we have shortly enunciated the main points of the plot which in recent years have captivated the attention of writers, thinkers, scholars and philosophers. To some extent, the *Matrix* reflects the philosophical discussion on reality and pseudo-reality or what was Morpheus's phrase “welcome to the desert of the real”. Professor William Irwin (2005) edited a book entitled *The Matrix and Philosophy* where he interrogates on the parallel between Neo and Socrates. Anderson wakes up in a reality he never thought about and he renounces to the comfortable wonderland he lived only by grasping the truth (Irwin, 2005). The spirit of the *Matrix* reveals two important things to our argumentation. On one hand, from Cartesian dualism onwards, philosophers have indagated on the role of scepticism to lay the foundations of scientific inquiry. The sense of truth can be tainted not only by mental illness but also by dreams which are “an uncanny state of the mind”, where reality is depicted beyond the scrutiny of the dreamer and their will. Although we may very well perceive the world around us in a dream as real, it is unreal. It is flourishing from our inner-life toward a mirror-like image. Of course, the sense of living, in reality, involves us entering into an existential pain, which not all can bear. This is exactly the dilemma in Cypher, who adopts a better life instead of a “real life”. This suggests that what is defined as “the real life” allows us to make decisions on a freeway, although our basic resources for survival are not granted or our well-being jeopardized (Irwin 2005). In consonance with this, David M. Nixon (2005) argues that believing is an act strongly associated to previous experiences in a way that sometimes leads us to

simulation. Neo not only believed he was living a real life, oddly with his experiences being fabricated by an evil machine (the Matrix) but paradoxically, he believes in Morpheus when he asks for knowing more about the real story. In this point, Carolyn Korsmeyer (2005) presents an interesting thesis which merits discussion. In her view, the *Matrix* triggers two different questions; one consists of asking what is real and valuable? and the second is, is what is real that which gives a more pleasurable experience?

The *Matrix* reminds us that what we see can be *the illusory product of a program*, but it paves the way for the rise of anti-Western rationalism that contradicts the hegemony of gazing as the best method to reach the truth. Western civilization has disposed of the *gaze as a metaphor for understanding* but things move from worse to worst, and the mind maddens if reality is perceived as it is. The betrayal of Cypher explains the urgency of forgetting the past and prioritizing the pleasure of the body over existential interrogation.

In a nutshell, Matrix puts in debate two important aspects of apocalypse. On one hand, the apocalypse should be understood as the rise of reality into the fictional world of immediate gratification, which is often constructed by humans. On another, sooner or later, this fake world melts in the air in the same way that the principle of reality takes from the slumber we are. This point was brilliantly assessed by Lord Raglan, who was one of the pioneers in the study of mythical heroes. Like Neo, the mythical heroes are blind to their promising future, and they were persecuted from their childbirth, even educated by other families abroad. Their royal lineage placed them in a real risk of being assassinated by the ruling monarch. In their mythical adventures, heroes face major threats and countless obstacles, which probes the human character (Raglan 2013). To some extent, Raglan amply shows how the archetype of the mythical hero fits with the needs of putting humankind into a test. This is the main discourse enrooted in the core of the theory of apocalypse.

As the previous argument is given, Wolfe enumerates some specific feats that the bottom-days narratives share such as the experience of the cataclysm, a journey through the wasteland created by the disaster, the settlement of a new community and the decisive battle to impose human values. A whole portion of novels reveal that the central character of the hero remains isolated when the disaster takes hit. This isolation was in view of an original fault, or simply as a moral punishment for an involuntarily crime. Almost all heroes are marked (if not cursed) by a sentiment of loneliness which ushers them in a depression or madness. The hero should travel far to understand the magnitude of cataclysm or simply due to a moral purgation for its personal offenses. This point is vital for a new community to be settled once hero defeats the forces of evilness reminding one more time why humans are so special. To cut the long story short, let's add that horror movies and apocalyptic genre were historically intertwined. As we shall see in the next, the archetype of heroism, as well as the hero's character, prevail in almost all plots.

The Zombies in Horror Movies

George Romero was the first film-maker who introduced the figure of Zombies in the horror movies. In the night of the Living Dead (1968) or Day of the Dead (1985), the intriguing double-edge of technology occupies a central role. For some reason, which is not specified in the plot, flesh-eating zombies populate the world pressing mankind to the extermination. The numbers of zombies outnumber humans 400.000 to 1. Dr Sarah Bowman and Miguel Salazar escape to Fort Myers, Florida where they (jointly others as Helicopter pilot John, or Bill). However things come worse to worst, and they are pressed to make way towards an army base located in Everglades. Once there, they are hosted by Captain Rodhes and Dr. Logan, who commands a group of scientists and militaries whose surgical experiment with Zombies. At this lab, these survivors devote considerable efforts and resources to domesticate (civilize)

the cannibalistic zombies. Sooner the tension between soldiers and scientists is evident and Rhodes ask their troops to destroy all the experiments in the lab. In an instance, Johnny -the pilot- invites Sarah to drink and relax while Sarah demands him to be unwilling to subscribe to neither side. He replies to her, that the world is exhausted humans should face the punishment of God because of their greed. Most likely, Johnny bets, the Lord imposed the mankind extermination to protect the earth he does not want to see how humans eagerly devour the natural resources. Beyond the extreme suffering, this evokes a renovation for the human race, and of course for the planet. The same can be found in *The Resident Evil 2*, where Umbrella Corporation manipulates a lethal virus that rapidly expands worldwide. The protocols of contention failed and sooner the virus widespread everywhere outside The Hive, the underground laboratory where everything started. Alice and friends struggle against this corporation without knowing she has genetically manipulated to be the “perfect warrior”. There are many commonalities between the two plots, which merit to be discussed. On one hand, the use and abuse of technology imply a great risk for mankind. The cannibal “living dead” return to life to eat human flesh while a bunch of survivors struggles to look another safer place to settle. The forces of evil and good enter in the last of battles, where the values that will reign on the earth are at stake. This mythical conflagration is accompanied by the needs of expiating the old human sins. Essential interests are the different matter in the plot of *Contagion* which emulates the latest Swine Flu (H1N1) outbreak in 2009-2010. After a business trip bound for China, Beth Emhoff (Gwyneth Paltrow) return to Chicago, US to have an adventure with her former lover earlier than going to her family in Minneapolis. She is married to Mitch (Matt Damon) who is not aware of her infidelity. The condition of Beth is suddenly worsened and it finally aggravates her death. Her six-year-old son dies as well. Though Mitch is placed in isolation, he and his daughter seem to be immune. Meanwhile, in Atlanta authorities and scientists of the Department of Homeland Security have a bolster with Dr. Ellis Cheever (Lawrence Fishburn) to coordinate future efforts to contain and respond to a lethal pandemic. Once again, the sense of fault is remembered according to the origin and rise of the apocalypse. *Contagion*, unlike *Resident Evil*, signals to scientists –not as the evildoers- but as the heroes who ultimately found and implemented a vaccine that saves millions of lives. The lack of contact between infected and healthy persons as well as the role of mobilities in the configuration of nation-state appears to be some of the topics this film deals.

Last but not least, another interesting movie where the archetype of bottom-days can be debated is *Noah*, a film starred Russell Crowe (Noah) and Jennifer Connelly (Naameh). At a first glimpse, the plot is developed in a grey post-apocalyptic landscape where *The Watchers* are punished by God once Semyaza led them to procreate with women. Their offspring, the Nephilim devoured the cattle and were prone to devastate the earth. God disposed of a deluge which purged the earth while Semyaza and his fallen angels were castigated. Aronofsky, Noah’s director, combines the *Chronicles of Enoc* book (see on *The Watchers*), with the classic biblical texts to offer a more than the interesting product. In this plot, the Watchers not only helps Noah to struggle against *Tubal-Cain* but they are the conduit towards the Lords plan to succeed. God asked Noah to fabricate an Ark, but he is decisively encouraged not to tell the god’s plan to Cain and his offspring. Noah should select a couple for species to continue with life. The ark contains not only the germen of life in the next world, prepared by God but also the future of humanity in the hands of Noah. The problem is that Noah is urged to keep the secret, witnessing how the human is ruthlessly obliterated through the articulation of a universal flood. This extinction became in the first genocide and Noah the architect of a new world where the sins of man are redeemed. The “shameful” Noah falls into depression and drinks all the time until God blesses the family as the new start of a re-born human race. Well, to here, we tried to remark the main common-thread arguments in four movies, which were broadcasted in different cultural background and times. Here two interesting

point should be outlined. First and foremost, as I noted in *The Rise of Thana Capitalism and Tourism* (Korstanje 2016), Noah was the biblical myth that not only influenced modern audiences but also remained to the passing of time. Noah's ark likely revalidates the assumptions that life needs from death. Because of this, Thana Capitalism rests on the dynamics of creative destruction in the same way Noah is the architect of the first mass cleansing. The drives of death, which today are canalized through dark consumption and dark tourism, are legitimated by this biblical narration. God disposes to exterminate humankind but in secrecy situating Noah as a privileged witness of his plans. Secondly, what lies beyond the message of this myth is the ongoing competence of liberal market, which places the rank-and-file worker inegalitarian conditions to others –who like him- will fight to impose his position. Unlike other productive systems, where human ties were stable and durable, capitalism gradually erodes the trust liberating the human relations to capital owners. This led to precaritize the workforce dealing with new emerging institutions. In the days Thana-capitalism, citizens reinforce their loyalties in their institutions and their auratic sentiment of supremacy by gazing at how others die. In TV programs, Magazines, Press, Realities, Novels, Movies and other sources of media entertainment, (even dark tourism), the others' death is systematically framed, packaged and distributed as the main commodity to exchange. We are obsessed to consume the suffering while by this rite we are safe at home. This happens because of two main reasons. As discussed in earlier sections, the process of secularization not only undermines the influence of religion and the belief in the after-life. Death and the act of dying to begin to be conceived as a sign of inferiority. It is important not to lose the sight of the fact the global audiences undergird their sentiment of supremacy while gazing (consuming) news of disasters, mass death, cleansing and other calamities. They feel part of the “chosen peoples” who are immune to the cataclysm. We toy with the belief this sentiment builds a strong narcissism, which unless regulated, may lead towards “chauvinist” reactions. We put the example of *Hunger Games*, Collins' novel, where each participant (tribute) keeps an overrated-image of itself while at the bottom all will suffer the same end. The rebellion only started when involved actors opt to cooperate with the other. The same applies to *Thana-Capitalism*, where the worker is pitted against the worker in a marketplace where few hands concentrate a whole portion of yielded wealth while a whole life with nothing. Last but not least, Narcissism, which is stimulated by hyper-consumption and aesthetics, is vital to understand the hegemony of the ruling elite. The meaning of apocalypse has a double-edged function. While lay-citizens valorize technology as the touchstone of modern society, its negative effects are not discussed. E. Snowden not only showed how a democratic government would vulnerate the individual rights to privacy, but also the uses of surveillance high tech when the ideals of democracy are subordinated to fear (Altheide, 2014; Skoll, 2014; Korstanje & Skoll 2018).

Future Research Direction

As declared, this paper is not originally aimed at triggering a debate to managerial or administrative issues. Rather, it focuses strongly on the role played by technology in the configuration of the end of the world. But what is the connection of this mythology with the economic world?

To some extent, our means of production, which are enrooted in the economic matrix that regulates society, are drawn by our myths and myth-formation. Far from being naïve stories told and retold by ancient tribes, myths represent real symbolic guidelines which help modern citizens to resolve their problems according to how their founding parents did. What is more important, myths are culturally created and circulated to resolve tensional problems or philosophical quandaries people are afraid such as the live, or death. The idea beyond the end of the world, as Eliade puts it, coincides with our own

preconceptions which led historically to organize labor in cycles of production and destruction. Basically, the use of technology tends to modify the territory but in so doing, humans need to deal with a sentiment of culprit. As administrators of the world, humans employ an abstract rationality to place order in the animal kingdom. However, the introduced technology not only alters the environmental condition of life, subordinating the natural world to the culture, but also creates a sentiment of self-punishment which is symbolically expressed in the belief the world should suddenly end. The question of whether the rationality exhibits an original sin which needs to be redeemed is not new, and of course it is not a monopoly of Abrahamic Faiths. Men are outstanding creatures enthralled to administer the nature, but in some extent they fail, and for that they should be punished. Last but not least, the reconstruction of human life, just after a disaster takes hit, has been commoditized and formed as a cultural spectacle which today captivates global audiences worldwide. The horror-movie industry just in post 9/11 days has appealed to the theory of the end of the world to domesticate the discontents and frustrations in the workforce.

CONCLUSION

After a further review, this chapter ignited an interesting discussion around the idea of the apocalypse or at the best to the role of technology by slicing humanity from nature. In terms of the British anthropologist Tim Ingold (2000), one of the conceptual limitations of “dwelling perspective” exhibits the clear-cut division of humans from the natural environment. Unlike hunters and gatherers who have developed “relational” ties with the sensual world, we are educated to imagine ourselves as administrators of the natural world. Because of this, the eco-friendly projects (as conservation parks) often exclude the presence of humans. The employment of technology denotes certain rationality, which while sorting the environment according to our needs, creates a sentiment of the culprit. The theory of apocalypse expresses the “original sin”, the sentiment of culprit which places human values in jeopardy. This happens because mankind, as an outstanding creature, is the only one gifted by Gods to administer nature, but inevitably failed. Moved by greed and speculations, men governed with energy in backs to God and for that, they should be heavily punished. As a result of this, the diaspora of survivors appears to be in quest of a new settling where humans give rise to the new cities, a type of rebirth that alternates the fear of coming back to the nightmare of past and the hope for a better future.

KEY TERMS AND DEFINITIONS

13

Capitalism: This is an economic system which rests on the principle of private ownership and the use of means of production towards profit.

Precaritized Labour: Low quality jobs offered in decentralized economies.

Technology: This represents the set of techniques, knowledge, skills, and actions oriented to transform the environment.

Thana-Capitalism: This signals to a new stage of capitalism where the gazing of Other's death is the main commodity to exchange. The term was originally coined by Maximiliano E Korstanje in his book *The Rise of Thana Capitalism and Tourism*.

Theory of Apocalypse: It is part of scatology, a subfield of mythology that explains and vaticinates how the world will end.

Software Literacy as a Vital Digital Literacy in a Software–Saturated World

INTRODUCTION

Software mediates almost every aspect of everyday life. Nearly all of our professional and personal activities are embedded and shaped within systems and interactions that involve software at some level; from the seductive ecosystems on devices such as smartphones or tablets, to the tools underlying everyday practices such as word processing and networked communication, through to the more functionally limited interfaces increasingly embedded into our homes and work spaces. None of these tools are ‘neutral’. They embody social and cultural assumptions about their use and all have particular values embedded in their interfaces and affordances. These reflect conceptual frameworks in which particular ways of acting or thinking are more possible and imaginable than others. Despite their ubiquity within contemporary society, software has only recently emerged as a field of study in its own right. As championed by the proponents of Software Studies this is a vital but neglected area of cultural production intersecting with and potentially shaping all other spheres of social, cultural, economic and political activity (Fuller, 2008; Johnson, 1997; Manovich, 2013). This article proposes the notion of ‘software literacy’ to highlight a neglected aspect of digital literacies, and a key means of conceptualizing the skills and understandings needed for people to be critical and creative users of software in today’s software-saturated culture. This contribution argues for the relevancy of software literacy as deeply intertwined with people’s engagement with software and how it influences the way people come to understand, represent, generate and critique knowledge.

The discussion below begins by overviewing the background and need for a focus on software studies before proceeding to define, introduce and elaborate on a framework for software literacy. An outline of the framework is then grounded in and exemplified through a case study located within a university teaching and learning context with implications for further thinking and research in the field.

BACKGROUND

The proliferation of digital and networked technologies is an expanding and accelerating feature of modern societies and can be predicted to continue to rise and impact on almost every sphere of human living. This trend is reiterated in UNESCO’s latest policy document calling for all countries to mobilize the potential of digital including mobile technologies “to strengthen education systems, knowledge dissemination, information access, quality and effective learning, and more effective service provision” if

DOI: 10.4018/978-1-7998-3479-3.ch113

they are to achieve the aspirational goal of inclusive and equitable quality education and lifelong learning by 2030 (UNESCO, 2015, p.37). Embedded within any digital device, software operates at multiple levels in contemporary life; as applications and platforms which we engage to facilitate and augment a host of social, economic and political practices, and less obviously as part of the taken for granted infrastructure of globalized cultural and economic exchange. We argue that software remains a conceptually neglected component of digital literacies, an often taken for granted aspect of the digital world which needs to be recognized as a distinctive part of contemporary literacies with its own dynamics and qualities which enable and constrain other literacies. Many practices within contemporary life, including those aggregated under the umbrella of digital, media and information practices are now ‘coded’ in the sense that they only exist and are constituted through programming code (Kitchin & Dodge, 2011).

However debates over terms such as information and communications technology (ICT) literacy, information literacy, digital literacy, media and information literacy, digital information literacy, and media and literacies studies tend not to acknowledge software as an actant in the world (Kitchin & Dodge, 2011) nor the emergence of software as a distinctive component of digital, media and information practices (Khoo, Hight, Cowie & Torrens, 2017). Our framework, software literacy, is intended to contribute to existing bodies of work on digital literacy (see for example, Ala-Mutka, 2011; Alexander, et al., 2017; Beetham & Sharpe, 2010; Hegarty et al., 2010; JISC 2014; Sefton-Green, Nixon, & Erstad, 2009; UNESCO, 2013). No studies to date that we know of raise the role of student understanding (including those who are new to using software) of how software and its affordances influence knowledge representation, generation and critique. Many studies have been conducted on information literacy and on ways of mastering software (Underwood, 2009), but the role of software itself tend to be taken for granted and is only now emerging as a field of study (Fuller, 2008; Lynch, 2015; Manovich, 2013).

Most people develop some level of proficiency with everyday software and hardware informally through their daily use and incremental engagement over time (Bulfin & Koutsogiannis, 2012; Hague & Logan, 2009). In educational research, informal learning practices have been shown to increase students’ sense of agency and consequently to have the potential to make learning a richer and more fulfilling experience (Furlong & Davies, 2012). Commenting on the trend of digital penetration, numerous authors have further argued that ubiquitous access to digital technologies has shaped a new internet-centred generation of ‘digital natives’ (Oblinger, 2003) with the corresponding assumption that access to digital tools has, on its own, facilitated the development of new learning skill sets (Tapscott, 2009). Terms such as the ‘digital generation’, ‘millennials’, ‘Net Generation’ (Tapscott, 1999), ‘digital natives’ (Prensky, 2001), ‘Google generation’, ‘Generation Y’ and so forth have derived from a host of assumption about the distinctive skill set of generations immersed within digital technologies. Such labels aim to characterize an emerging class of learners accustomed to engaging with software and other digital technologies such that they can effortlessly adopt such technologies, operate at ‘twitch speed’, are able to multitask, imagine, and visualize while communicating in multiple modalities and consequently possess higher technical skills compared to previous generations (Prensky, 2001). The term ‘digital natives’ itself assumes a generational change in digital literacies fed particularly by informal learning, opinions which are closely informed by emancipatory rhetoric surrounding the digital. As it has become used more colloquially, ‘digital natives’ suggests an inevitable increase of technical proficiency which is acquired through immersion within the digital world. Young learners are assumed to use trial and error, and an ability to network easily with peers to transfer knowledge, in the pursuit of skills which can translate to any new digital device. Implicit within this model of informal learning is the assumption that a user who develops a proficiency in one software application will be able to easily apply these skills to other forms of software.

We argue that these assumptions do not sufficiently acknowledge either the complexity of factors shaping digital literacies or the manner in which software itself ‘evolves’ in complex combinatorial patterns. For example, common affordances such as copy, cut, and paste are assumed to be naturalized and embedded across different software applications and able to be picked up with ease by this current millennial generation for work and leisure pursuits. However these affordances are poorly understood as tools contextualized within larger hierarchies of affordances and interfaces that shape both their use and more broadly people’s engagement with knowledge, culture and society in the 21st century (Livingstone, Wijnen, Papaioannou, Costa, & Grandio, 2014). Software is also poorly understood as the product of particular industrial practices, just as with other forms of technology. The more sophisticated software applications contain complex hierarchies of affordances which are regularly updated by their designers. These hierarchies in turn embody conceptual frameworks which represent a host of assumptions made by software engineers about how these applications might be deployed by users. Software development tends to have its own trajectories governed by the economic, technical and personnel dynamics of software companies. Many common forms of software, for example, demonstrate an ‘affordance creep’ over time; the multiplication of affordances and increasing complexity of interfaces that are not necessarily tied to user demand. Software, then, evolves in patterns which continually challenge users’ existing skills and understanding.

In part the term ‘digital natives’ also articulates anxieties amongst educational institutions and practitioners that they are falling behind the literacies students will bring with them to learning contexts. Educators are often encouraged to operate under the assumption that students already possess the necessary computing skills and conceptual frameworks to learn with and through generic software packages, and tend to neglect the role which software affordances themselves play in shaping how students actually ‘perform’ that software (Adams, 2006). Research indicates that such assumptions about students’ digital proficiencies are unfounded and that digital inequalities and marginalization persist around students’ access to, and use of, information and knowledge (Bennett, Maton, & Kervin, 2008; Jones & Czerniewicz, 2010; Kennedy et al., 2008). There needs to be more attention paid to distinctions between different kinds of skills and understandings within the broader digital literacies umbrella, and how these are informed by a variety of other factors in student learning. There is evidence students may not be aware of how to apply software embedded technologies effectively to enhance their learning (Khoo, Johnson, & Zahra, 2012; Valtonen, et al., 2011). In other words, digital inequality may not be defined specifically to the issue of *physical* access to digital tools (software and hardware) but may be intimately shaped by each learner’s ability to learn and apply such tools in ways which similarly constrain learning and access to knowledge, and, deeply inform the nature of any agency which an application enables. One obvious implication is that the expectation of teaching and learning institutions should perhaps be that individuals may be more or less able to exploit and critique the affordances of software and hardware (Selwyn & Facer, 2007). A student cohort where everyone has access to digital technologies does not necessarily mean that they have all naturally acquired the literacies to usefully apply, and critically engage with, those technologies. Inequalities also arise due to differences in the social and cultural support for digital use.

Labels such as ‘digital natives’ tend to conflate a basic skill in operating new technologies with broader forms of understanding and the ability to critique aspects of technology-based cultures. It is important to challenge these stereotypes and assumed competencies in order to examine the range of skills and other literacies that today’s students bring (and do not bring) to their tertiary learning. Students may not be aware of the full implications of the affordances and constraints offered through particular software; students may be as likely to be ‘captured’ by specific applications as ‘empowered’ by them. The design of software necessarily enables some practices even as it constrains and marginalizes others. An awareness

of the nature, rationale and implications of different software becomes more vital in situations where platforms and applications are assumed by their users to be ‘neutral’ tools.

Educators know very little about how students develop the skills and expertise needed to attend to the features and use of software (as application, platform, and infrastructure) in the service of completing basic and complex learning tasks. There is evidence that students adopt a range of informal approaches to meet their learning needs due to the proliferation of digital and networked tools (Peeters et al., 2014; Khoo & Cowie, 2018). Research also indicates that students’ formal software learning backgrounds are diverse (Khoo, Johnson, Torrens, & Fulton, 2011). As with other tools employed during learning, student knowledge and use of software and hardware is highly specific to their formal and informal educational, social, and cultural contexts for learning and use (Jones, Ramanau, Cross, & Healing, 2010; Valtonen, Dillon, Hacklin, & Väisänen, 2010). There is a need for further studies to raise educators’ awareness of the role that software plays in shaping and framing what and how they teach and its effects on student learning. In particular, educators can benefit from ideas and guides that help them to interrogate and reflect on their own practices - to facilitate more effective pedagogies for teaching and learning with, through and about software (including raising their students’ awareness to similar issues).

SOFTWARE LITERACY

Software studies, a comparatively new field of enquiry, proposes that ‘software’, which encompasses many forms of computer programming, is the dominant cultural technology of our time (Fuller, 2008; Johnson, 1997; Manovich, 2013). Manovich argues that we need to “think of software as *a layer that permeates all areas of contemporary societies*” (emphasis in original, 2013, p. 15), a feature of all contemporary social and cultural practices which has been comparatively neglected as an object of investigation. In an era in which our daily work routines may revolve around the use of a set of naturalized creative and communicative applications, when most social, cultural and political communication is embedded within and deeply informed by social media platforms such as Facebook, YouTube and Twitter, and a plethora of software applications run in the background of all major institutions, ‘software’ as a collective needs to become the target of greater investigation. A core premise of software studies is the need to recognize the role of software operating at a variety of levels to shape the nature of our institutions and our everyday lives. In other words, there is a vital need for software users (i.e. the vast majority in modern societies) to develop a more critical awareness of how software operates to both “empower and discipline” our social, economic, and political practices (Kitchin & Dodge, 2011, p. 10-11).

These are obviously core issues for educators but given the increasing role of software within everyday life such concerns also contain lessons for software users more widely. For instance, Adams (2007) argues for the development of more informed epistemologies of practice and advocates for software design principles that are more sensitive to pedagogical practices. And Lynch (2015) critiques the long-standing tendency to adopt new technologies without considering the deeper implications of their use to call for further investigations into the “hidden ways issues of ideology, power, and inquiry are encoded in educational software spaces” (Lynch, 2015, p. 50). Others such as van Leeuwen and O’Halloran (2011) underscore the need for software literacy modelling and use by educators and students. Being more critically aware of these aspects would allow educators and students to become more informed users of software (Vallance & Towndrow, 2007). This awareness can lead to opportunities for more equitable exploration and dialogue concerning the social, cultural and technological forces that shape the way in which knowledge within a formal discipline is developed, shared and communicated and the

implications of these aspects for teaching and learning practices. The proponents of Software Studies have tended to focus on deconstructing particular kinds of software as part of a broader effort to develop a genealogy of software as a cultural artefact - Manovich, for example, has engaged in the vital task of analyzing sophisticated media editors such as Adobe After Effects (Manovich, 2006). There remains a pressing need for empirical studies which investigate how skills and understanding around specific forms of software are acquired and applied by diverse groups of users.

In order to extend this line of research the term ‘software literacy’ is proposed and defined as the expertise in understanding, applying, problem solving and critiquing software in pursuit of particular learning and professional goals (Khoo, Hight, Cowie & Torrens, 2017). We use the term ‘literacy’ to direct attention to how individuals make use of software and for what purposes, in what contexts and with what anticipated and unexpected outcomes. Our notion of software literacy is grounded in a practice-based framework which aims to identify what distinguishes a novice user from an expert user through proposing a progressive transition from novice to expert-like understanding, capabilities and qualities (Jones, 2008; Livingstone, et al., 2014). Our framework clarifies three progressive tiers of development towards software literacy. They are:

1. A basic skill level where a learner can use a particular software. This typically means using common affordances provided by default at the top level of a hierarchy of affordances (for example, cut, copy and paste functions which tend to be featured in prominent positions within many interfaces for creative and communication applications),
2. An ability to independently troubleshoot and problem-solve issues faced when using the full range of affordances constructed by the software. When teaching software this is a key threshold reached by students; the point where they recognize their own novice level of proficiency in using an application but are able to identify and make use of resources which can allow them to understand and apply further sets of affordances. For more sophisticated forms of software, users may never achieve a level of ‘mastery’ over an application or system (they may not know of, understand and can apply each and every one of its affordances). And they may find their existing skills and understanding continually challenged by periodic updates to its hierarchies of affordances and/or interface. But these users nevertheless have acquired the ability to problem-solve how to apply that software to new tasks.
3. And finally, the ability to critique the software, including being able to apply such critique to a range of applications designed for a similar purpose and to further use these understandings for new software learning. In immediate terms, users at this level have an understanding of the conceptual framework underlying an application; i.e. the archetypal user it is aimed at, and the kinds of practices it is primarily designed for, and hence what that application might or might not be most usefully directed towards. Users at this level, then, develop a knowledge and an understanding of a range of software and what is ‘useful’ for particular kinds of tasks.

Implicit within this tiered framework is also a graduated sense of how users’ agency is enabled and constrained through their use of software in different contexts. At the first tier, users are more likely to adapt their existing practice to suit what they are able to achieve using an application. Successfully completing a specific set of tasks might be all that these users require and they might see no need to explore that software further. In a sense, these users might be seen to have been ‘captured’ by that particular application; they are yet to develop a richer awareness of the possibilities to deploy that software

for other purposes, nor have an understanding of how competing applications may offer different possibilities for their existing practices.

Users at the second tier can be assumed to have developed greater agency in relation to an application or platform. Enabled by their ability to troubleshoot when they encounter difficulties in making the application do what they want it to, they are perhaps more likely to feel empowered to explore the wider possibilities of that application. Users at this level appear to also be more likely to start using a software application or platform in ways that would be surprising to its original programmers. Moving beyond the assumptions about core users held by that applications' designers, they are able to use an application in ways that move beyond the default practices most easily enabled within its hierarchy of affordances.

Finally, users at the third tier of software literacy are assumed to be able to explore their agency across a range of software applications or platforms. As more critical users of software, they are more likely to develop an awareness of the range and variety of practices which are enabled and constrained by particular sets of software. They potentially have the ability to understand what an application means in detail for their particular practices; that is, what each application offers them, what each application 'does well' and what it does poorly. They have agency to pick and choose the software tools that are most appropriate for a specific practice and to apply sets of applications together toward particular ends. They understand the imperfections of any given piece of software but also the ways in which these might be used for their own purposes. For those users who develop a 'mastery' in a particular sophisticated set of applications or platform, they are capable of generating a critique of that software as it evolves over time (over a series of upgrades). Where a user at the first tier of software literacy might not be able to easily move from one application once they achieve a basic proficiency in its use, users at this third tier are much more easily able to 'abandon' software which is no longer useful and to commit to learning a new application or platform, and to more easily apply acquired skills and understanding toward this end.

A key point to emphasize here is that these three tiers are intended as reference points for thinking through software literacies. There is inevitably a fluidity and flexibility across these tiers for any group of users. Any single user, for example, might operate across more than one level, having gained basic proficiency in one application or applications but not necessarily having the ability to immediately transfer this skill set to another kind of application or platform. Complex applications tend to develop their own hierarchies of affordances, and are not necessarily easily understood by new users, even those with some skill in other forms of software. For example, gaining a mastery of the Adobe Creative Suite does not mean that users have therefore also achieved a mastery of other complex software applications such as Computer-Aided Design systems.

This framework also assumes a variety of skills and understandings are constituted in what it means to be fully 'literate' in software. A key threshold within tier 3 is the point where users are able to transfer a critical understanding of software affordances and use to new software and to familiar software in new contexts and situations. This knowledge might be relatively contained to a specific set of applications that a user encounters most often - such as students acquiring a rich and nuanced awareness of the kinds of applications which, inform, enable and can extend their practice within a particular field. Many but perhaps not all of these users can be assumed to then have the sophisticated understanding needed to consider how software (at various levels of application, platform and infrastructure) more broadly shapes, enables and constrains the particular kinds of knowledge and actions that are readily available to them. At this level, students (and by extension, citizens) are assumed to be capable of recognizing more broadly the role which 'software' plays in various levels within contemporary life, and to more deliberately choose platforms and applications based on a thorough understanding of the conceptual and practical implications of their choices. As with other forms of digital literacies, this third tier accentuates

an essential ability to ‘critique’ software as it appears more broadly across other everyday practices. This is an attribute also recognized by other researchers as a key characterization of 21st century learners and working professionals to participate productively in the political, economic, leisure and social spheres of everyday life (Gilbert 2005, Jenkins et al. 2009, UNESCO, 2015).

Developing one’s software literacy relies on a combination of general competency with software and technologies, together with the ability to undertake more independent (especially informal) learning of discipline-specific knowledge as and when required. This conceptual framework is a response to current digital literacy frameworks and related terms which do not go far enough to identify the implications of the choice of software applications and platforms on what can be achieved (Hegarty et al., 2010; Livingstone et al., 2013). The software literacy framework outlined here is intended to complement existing research on digital literacies; to more properly acknowledge the emergence of software as a cultural artefact possessing agency within social, cultural, economic and political practices (Fuller, 2008; Johnson, 1997; Manovich, 2013).

SOLUTIONS AND RECOMMENDATIONS

The potential of our three-tier software literacy framework was evidenced through a case study of university context teaching and learning environment. The aim was to explore, examine, and theorize on how the notion of software literacy is understood, developed, and applied in university teaching and learning contexts, and the extent to which this understanding is useful when translated into new contexts of learning with and through software (Khoo, Hight, Torrens, & Cowie, 2016). To address this broader aim, the study, confined to the disciplines of media studies and engineering, sought to explore the nature of informal and formal learning of software applications as an entry point in investigating the nature of software literacies fostered within distinct tertiary student cohorts. The study initially focused on student learning of PowerPoint as a generic form of software application, typically learned partially or wholly through informal learning, before progressing to examining student learning of disciplinary-specific software learning in media studies (e.g. Adobe Photoshop, Final Cut Pro), and engineering (e.g. SolidWorks, a 3D computer-aided design (CAD) application). Within both these disciplines, PowerPoint was a common feature of lecture sessions, but not specifically examined as software. While engineering students were required to learn SolidWorks as part of disciplinary knowledge, the media studies students encountered software as part of production electives within a broader degree programme and were encouraged to use a range of applications as needed for creative projects. Each of these disciplines required students to apply professional-level creative and editing applications toward learning tasks, and provided detailed instruction in software which was both comparatively complex and relatively unknown to incoming student cohorts. Each disciplinary context also provided distinct sets of knowledge about software provided to students, contrasting experience with a range of alternative applications to those taught in workshops, but nevertheless shared expectations of the need for students to employ informal learning to complete their understanding of specific pieces of software. The overall objective was to understand the impact of more direct instruction (of sophisticated software applications) on student software literacy development and disciplinary understanding.

The findings of this study support the existence of the three-tier software literacy framework but indicate there is some flexibility in student development and movement between the tiers. It was demonstrated that student ability to achieve the higher tiers of software literacy did not preclude them from needing to revisit earlier levels in contexts where they encounter new but similar software. As such,

developing a relatively sophisticated and critical understanding of an application or platform does not necessarily transfer directly to the learning of other forms of software. This suggests educators should not assume student competency with software across contexts (e.g., informal to formal, from campus to workplace settings). The framework provides a key conceptual tool for practitioners in terms of understanding the role of troubleshooting, for example, as an important development stage in learning with and through software.

There was evidence of students having arrived at tier 3 (critical literacy) as well as those not moving beyond tier 2 (troubleshooting). For example, student (mis)assumption that the course lecture notes presented in PowerPoint's bullet point format in and of themselves constitute an adequate elaboration of pertinent disciplinary knowledge. The affordances and constraints that PowerPoint and discipline-based software offer in shaping disciplinary knowledge needs further consideration by students and by educators. Educators therefore need to be aware of the implications of their choice and modelling of a software application or platform. Findings suggest they would be wise to introduce and help students to develop critical awareness of how such software can inform and shape their own understanding of disciplinary knowledge and practice.

These findings were manifested in distinct but closely aligned patterns within each disciplinary context. However, there was also a difference in the way each discipline prioritized software literacy development as part of their student learning pathway and graduate profiles. For example, in the media studies case, critical thinking as emphasized in the third tier is seen as a core aspect of creative disciplinary knowledge. Being able to judge the creative capacities of competing software has implications for the nature of the practice which is being developed, the form and eventual conceptual complexity of media products themselves, as well as more practical considerations such as budget. In contrast, in the engineering case, students are expected to develop digital and software literacy skills as part of their professional learning. For graduates, the quality of engineering design produced and a design's efficiency and effectiveness are prioritized over the kinds of creative reflexivity observed in the media studies case study. Such disciplinary differences reveal a need for each discipline to continually reflect upon how discipline-specific software teaching and learning is positioned in relation to graduate profiles and the breadth and depth of literacies required to engage successfully with software.

Another clear finding reiterates that multiple learning pathways exist for exploring the affordances of any particular software, both formal and informal. Students tend to prefer informal strategies as a supplementary to and at times above formal strategies to learn discipline-based software (these included YouTube video tutorials, along with peer networks) (Khoo & Cowie, 2018). Educators could usefully be informed by and take advantage of students' informal repertoire of learning strategies and networks including their accessing of (web-based) resources and pooling of peer expertise. Educators drawing from students' already established informal learning strategies would recognize the relevance of the social and cultural context in shaping effective technology and software engagement.

The findings importantly challenge current notions and assumptions of the digitally literate generation. When learning to use PowerPoint most students perceived themselves to be competent and confident early adopters of technologies and could identify the general affordances of generic software (PowerPoint) to the extent of critiquing the design and performance of PowerPoint practice in their lectures. They were able to recognize discipline-specific affordances among the applications formally taught and acknowledged these to be central in their engagement with disciplinary knowledge. However, very few were able to critique how the design of the 'software' itself might shape their disciplinary knowledge. Very few students demonstrated critical thinking about the nature and role of the software they were using and most were not able to describe or discuss applications beyond those used in their learning. That is, there

was very little evidence of tier 3 software literacy. Students' superficial critique of software challenges current assumptions that today's students as 'digital natives' have developed critical awareness simply through familiarity with and regular use of a variety of everyday applications and platforms.

The diversity of student cohorts and the range of understandings and the variation in familiarity, skills and experience students bring with them to the formal software learning context constitute a further challenge for teaching of, through and about software. Some students may already have a critical orientation towards software (or, more frequently, toward specific applications). And there is demonstrably an advantage in terms of more advanced software learning for those who have prior experience with other software with a similar conceptual framework. In response to this diversity educators could usefully direct time and attention to formatively assessing students' initial software literacy and adapting teaching activities in light of this. Most crucially, however, the overall findings indicate there is no single best approach (one size fits all) to teaching discipline-specific software. Educators adopting a range of teaching approaches (formal and informal) and being flexible to address diverse learning needs represents a crucial part of supporting student learning.

FUTURE RESEARCH DIRECTIONS

Software is a site of cultural production and an actor in social, economic, political practices; it needs to be analyzed in terms of its embedded values and effects on such practices. The brief summary of case study findings outlined above is limited due to the situated nature of the investigation into discipline-specific software teaching and learning. The participants in the study represent a convenience purposive sample of educators and students from one educational institutional setting. They were from two distinctly different disciplinary contexts, with distinct and different disciplinary foci and expectations of software teaching and learning. Educators were also careful to point out the study only focused on some courses within a program and all universities have different interpretations of how software teaching and learning can be enacted. Many educational practices are now intimately associated with software-based tools and applications, suggesting an urgent need for research which explores the implications for such practices and the manner in which they operate and are embedded within specific institutional, disciplinary and learning contexts.

CONCLUSION

Software literacy is an essential part of learning and living in the 21st century; something which transcends the use of any particular tool and any particular educational, social and cultural context. Software is an increasingly central part of the palette of understandings and skills which comprise the broadening umbrella of digital literacies. The software literacy framework outlined here offers a basis for addressing the social and cultural dimensions of software-centered learning, including the interactions between formal tertiary environments and informal learning networks.

The research outlined above addressed a tertiary educational context and a focus on specific sets of applications already embedded within existing industrial practices (from creative workflows suggested by media production practices, through to the 3D CAD practices that are widely used across design, architecture and engineering industries). Outside of this formal learning environment, software offers a challenging and rapidly evolving part of contemporary life. Everyday applications used for word

processing and other creative and communication practices generate a low-level demand to maintain skill proficiency in the face of continually updated software packages. Software interfaces are proliferating across a variety of other aspects of everyday spaces, from control panels for services in the urban landscape, to their increasing ubiquity across household appliances and a host of everyday encounters within retail, transport and entertainment services. These also have implications for practices that are at the core of and related to how knowledge is generated and curated. Contemporary museum and library environments, for example, are increasingly constituted through software platforms - in ways which are not being researched as rapidly as they are being pursued.

Other examples of how software tools can influence the way we live are not hard to find. There is an increasing reliance locally and internationally on a host of practices and specializations within the field of data science (such as the use of arrays of sensors to generate data fields, data mining and the new frontier of deep learning). These are being used within policing, environmental, agricultural sectors for making sense of data in ways which can inform and drive policy and funding decisions. Newer media platforms such as augmented reality (AR) and virtual reality (VR) (collectively referred to as XR) have yet to become as fully embedded within education, entertainment and knowledge industries as they are within military-industrial contexts, but AR is increasingly a default platform for training practices and on-site support materials across a huge range of applied practices (from mechanical to medical). As of this writing there are a host of experimental applications which provide cultural encounters for users which are fully encased within dynamic, fluid and rapidly evolving software environments within the XR spectrum. More seriously, the threshold for access by everyday users to increasingly sophisticated creative production platforms is becoming lower, at the same time as the more disturbing implications for some of these platforms are becoming clearer. There is already unease, for example, around the potential of 'deepfakes', a form of audio-visual production aligned to machine learning techniques which allows the easy generation of fabricated video content. Public figures particularly within the United States have been early targets but commentators are speculating on the implications for all of us if these forms of 'synthetic' media are added to an existing online climate of misinformation and disinformation (Marwick & Lewis, 2017; Wardle & Derakhshan, 2017).

There is obviously a pressing need for all of us as citizens to have a critical understanding of software to allow us to make more informed choices about their use, to enable us to transfer this critical understanding to software we have yet to encounter, and most crucially to understand that all software has nuanced affordances and limitations. This has implications for education providers, especially universities, in their role in fostering critical thinking and serving as a key critic and conscience of society. It is crucial to ensure all students and educators are supported in teaching and learning processes when these are mediated through and focused on software. As society moves to exploit the potential of a range of 'coded' practices there is a need for further detailed empirical investigation into the extent to which learners of applications, platforms and infrastructures become software literate. In formal and informal settings this is needed to ensure equitable and critical learning with, through and about software.

KEY TERMS AND DEFINITIONS

Affordance: A person’s perceived opportunity to utilise a particular tool for action, for example, a doorknob is for turning. Within software, these are typically organised through user interfaces.

Digital Literacy: An umbrella term for a number of competencies, skills and understandings associated with digital infrastructural technologies (we argue software literacy falls within this same umbrella).

Pedagogy: Study and practice of teaching.

Software: Machine readable instructions which directs a computer’s processor to perform specific operations. For everyday software applications, these instructions are put into operation as users run an application on any digital, networked, or mobile device.

Software Application: A computer program designed to perform a set of tasks or functions. Common everyday examples range from an ‘app’ on a smartphone, to desktop computer programs such as a web browser.

Software Literacy: A person’s expertise in understanding, applying, problem solving and critiquing software in pursuit of particular learning and professional goals.

Software Platform: A coherent programming environment or system which supports applications. Examples include operating systems such as iOS or Android, or social media platforms such as Facebook.

ICT Investments on Economic Sectors With International Comparative Advantage and the Diffusion of Prosperity

INTRODUCTION

It is well documented in the scientific literature that countries facing economic crises, or the years following that difficult period, need extensive investments (domestic or foreign) in various economic sectors in order to re-gain their international competitiveness and to trigger long-term and viable economic development. Such investments are critical factors to increase nation's GDP, further reduce unemployment rate, increase purchasing power and spread the benefits of economic prosperity across all levels of society. A crucial aspect is to examine to what extent information and computer technologies (ICTs), as they incorporated in this investment process, can accelerate and leverage the positive impact in the economic circuits and provide an added value in the economy. Certainly, such investments would be highly effective to take place in economic sectors that appear international comparative advantage in conjunction with relative interventions in public sector.

It has been long investigated and empirically proved worldwide that adoption of information technologies from private and public sector can provide immediate, direct and indirect benefits in short and medium-long term basis. As a demonstration of this we will examine the case of Greece, a country that faced an unprecedented economic crisis for the western world standards, and we will explain how adoption of information technologies can be realized in both the private and the public sector, so as having a positive multiplying effect in economy with positive results for the whole society. Through this analysis, we shall underline the importance of ICT investments on economic sectors with comparative advantage in Greece that potentially can accelerate the current economic development trend and provide solutions that will create income and opportunities for all, especially for the new generation.

BACKGROUND: ECONOMIC CRISIS IN GREECE (2009-2017)

Before analyzing the main topic of this article, it is fundamental to briefly mention the background of Greece in terms of the economic crisis. Greece has been chosen as a unique example of a western world country that has been suffered an economic crisis of such magnitude. Economic crisis triggers negative social phenomena across all levels of economic function. Indicatively, the country under crisis suffers reduced GDP (Gross Domestic Product - the total amount of values produced in economy in a year)

DOI: 10.4018/978-1-7998-3479-3.ch114

that is usually translated into potential personnel reductions (or in the best case there are no new hirings), decreased salaries and pensions and reduced budget of public investments (new roads, hospitals, schools, etc.), amongst others. Accordingly, in the private sector, firms face reduced demand for their products, difficulties in borrowing money from banks, increased tax payments and other negative facts that lead them to reduce personnel, reduce their program of investments and holding money because of the uncertainty prevailing in economy.

The figures that follow clearly depict the impact of the crisis on the fundamental economic figures of Greece. These figures indicate the economic tunnel that Greece has been through for almost a decade with major implications in society and in economy.

Figure 1 shows the Greek GDP over the last 40 years. The Greek economy, achieved a historical economic progress from 1974 onwards, which violently halted in 2009 signaling the collapse of the economic process. Greece, from 2009 until 2016, lost almost 25% of its income.

Figure 1. The evolution of the Greek GDP over the last 40. Source: World Bank, Gross Domestic Product for Greece [MKTGDPGRA646NWDB], retrieved from FRED, Federal Reserve Bank of St. Louis; <https://fred.stlouisfed.org/series/MKTGDPGRA646NWDB>, June 13, 2019.

Figure 2 shows the same negative situation in terms of income per capita, indicating the worsening of the life-conditions for the Greek citizens.

During the same period, one of the most negative implications in such a difficult economic environment was the sky-rocketing of unemployment rate, which touched the level of 28% in 2013. This is clearly shown in figure 3.

The previous figures illustrate the unprecedented magnitude of the economic crisis in Greece and its dramatic impact on society. Those figures show the recessionary background of the Greek economy and the same time the starting point for the future challenges and prospects lie ahead and that will be analyzed over the next chapters. The dimensions of the crisis in Greek economy are not in the scope of this article [the interested reader should consult (Papadopoulos & Syropoulos, 2018) for more details].

ECONOMIC MOMENTUM

The opposite of crisis is economic development. The term “development” means the expansion of an economy and the increasing of the level of wealth and the level of well-being in society through new well-paid jobs and new public and private investments, amongst others. Especially for Greece, after a long period of 10 years in crisis, economic development is a one-way road for the future of the country.

Many opinions have been expressed in public dialogue and in scientific literature about the necessity for a strong and viable development to be triggered in the Greek economy after so many years of recession and dramatic social implications. But how this economic development can be realized? Certainly, the key-word here is the term investment. Development of an open economy can only be achieved through investments which accelerate and multiply the economic growth. In simply words, an investment is a dedicated amount of money used to create something, with the hope that this will return in the future a profit supporting the economy in its expansion. Investments are separated in public (roads, schools, energy infrastructure, hospitals, etc.) and in private ones (new buildings, new businesses, new production lines, collaboration with public sector, etc.).

Economic rationalism and most modern economic theories underline the fact that investments should be realized in sectors that appear historical and/or potential comparative advantage at a regional or international level. In this way, investments could achieve a high efficiency and a significant profitability rate leading the economy to higher levels of balance with better opportunities for all citizens to improve their lives. The only question here is the following one: Is Greece ready to proceed to that kind of investments through a nationally accepted strategic development plan? Figure 4 shows the evolution of the 10year Greek government bond yield. After the tremendous levels of 2010-2013 and 2015, a constant downward trend has been initiated from 2016 onwards indicating a relative stability in the Greek economy and the regaining of the trust from the global investors about the prospects of the Greek economy.

Figure 4. Evolution of the 10y Greek government bond yield. Source: Organization for Economic Co-operation and Development, Long-Term Government Bond Yields: 10-year: Main (Including Benchmark) for Greece [IRLTLT01GRM156N], retrieved from FRED, Federal Reserve Bank of St. Louis; <https://fred.stlouisfed.org/series/IRLTLT01GRM156N>, June 14, 2019.

In addition, figure 5 shows the general trend of the exports in Greece (goods & services) from 1996 onwards. The most impressive and promising for the future dimension here is that Greek exports, after the crisis shock in 2009, are constantly increasing their magnitude in terms of value. This indicates the extroversion of many Greek companies even in the middle of the crisis and the adjustment of those firms in this new and challenging environment.

Figure 5. Evolution of exports of goods and services in Greece. Source: Organization for Economic Co-operation and Development, Exports of Goods and Services in Greece [GRCEXPORTADSMEI], retrieved from FRED, Federal Reserve Bank of St. Louis; <https://fred.stlouisfed.org/series/GRCEXPORTADSMEI>, June 13, 2019.

Finally, the Greek fleet (dead-weight tonnage), which is the biggest in the world [see (United Nations, 2018)], and tourism are two economic sectors with significant comparative advantage at international level. In particular, Greek tourism (see figure 6) shows constant increase in arrivals and receipts over the last years.

All previously mentioned critical elements strongly indicate that for Greece now is the right momentum to come back to a strong economic development after so many years in economic crisis. Additionally, one might say, that this development can now be conducted under better terms than the development that was taken place before 2009 because of the massive reforms that have been made in public sector along with relative legislative production.

The only crucial issue here is that Greek politicians must realize and set to implementation a holistic and strategic, national scale development plan. One that will use the right resources and ICT investments at sectors with international comparative advantage that eventually will trigger strong economic development. This development must be guided at a direction that will reinforce social cohesion, reduce inequalities while in the same time will create high quality well-paid jobs with prospects.

Over the next sections, we will focus exactly on this kind of analysis, meaning that a viable and strong economic development can be triggered by using extensive ICT investments in sectors with comparative advantage in Greek economy.

HOW TO ACHIEVE ICT COMPETENCE

In order to produce personnel, scientists, and engineers who have exceptional ICT skills, it is necessary to design a national educational strategy that will provide the required knowledge. This means that all primary education pupils will have to learn a number of topics in order to be able to deepen their knowledge later in middle school, high-school, and university. Currently, Greece does not have a curriculum

Figure 6. International tourist arrivals, 2012-16. Source: OECD Tourism Trends and Policies 2018 (data from <https://dx.doi.org/10.1787/888933639474>).

13

that aims to make pupils well versed in ICT. Instead, ICT lessons are considered something where pupils take it easy. In addition, the grading system makes it impossible to give fair grades and so only very few pupils who are really interested in ICT do participate in any kind of school actions [this a more general problem that is described in full detail in (Côté & Allahar, 2007)]. The worst part is that the university admission system is designed in such a way that students are admitted to university departments that have nothing to do with their skills and their background. Naturally, this has to change.

The modern trend is to use Open Source software so as to reduce the cost of computer systems. In addition, this will create an ecosystem where people will work to improve software and/or create new software to solve existing or new problems. Thus, we favor an educational approach that uses a set of Open Source programs and tools as learning vehicles. Naturally, this includes Open Source operating systems (e.g., Linux, OpenBSD, OpenIndiana, etc.). Thus, pupils of elementary education should be able to prepare documents, spreadsheets, and presentations. Depending on the available resources, one can use little robots or anything else (i.e., Kojo) to introduce pupils to LOGO style programming. In middle-school, pupils should be introduced to programming. We think that Python is a good tool to introduce pupils to programming. In three years time, one can start from very simple topics and go on with GUI programming which is both more demanding and rewarding. At high-school, pupils who aim to study information sciences and related fields, should get a deeper understanding of a number of topics [e.g. script programming with Scala (Loverdos & Syropoulos, New York)], while all pupils could be introduced to HTML and related technologies. Even learning how to use LaTeX [e.g., see (Syropoulos, Tsolomitis, & Sofroniou, 2003)] would be quite beneficial for pupils.

COMPARATIVE ADVANTAGES, ICT ENHANCEMENT & ECONOMIC DEVELOPEMENT

ICT investments on sectors with international comparative advantage can firstly triggering and later on accelerating economic development. This is so, because based on economic theory approaches, comparative advantage means that a country can produce added-value easily since the production factors (Labor, Land, Capital) are cheaper to acquire and use in the production process. This is the core of a viable, long-term economic development since the Greek economy can exploit a double nature: sectors with international economic comparative advantage with the assistance of ICT investments. ICT investments in such sectors can certainly facilitate and accelerate the economic process. Such technologies could potentially include e-tools for the support of exports companies, e-tools to improve agricultural methods and productivity, online banking tools interconnected with public authorities and finally tertiary level education e-platforms and e-tools for remote education solutions. Additionally, we can add in this list massive investments on renewable energy networks that are centrally and electronically supervised at a national level so as to maximize productivity and allocation of benefits, or new generation e-platforms for tourism to promote attractive and under-advertised destinations-disruptors along with real-time reservation abilities. As for public sector this approach could include total interconnection of public organizations so as fully eliminating bureaucracy, and central control of tax evasion.

In what follows we will describe in a more detailed way the previously mentioned sectors that can be benefited by an ICT investment which can increase efficiency and productivity. The following indicative sectors of the greek economy can potentially be exploited under the best economic terms.

- Exports** In the previous section, we presented the positive trend for Greek exports even during the years of crisis. This means that many Greek companies managed to increase their sales and profits by investing in their future through exports to other countries. This process can be further enhanced and accelerated under a common electronic platform at a national level which will support all firms whose primary turnover comes from abroad. In this platform, all export companies and new companies that have the ability to directly route their production to Exports, through ICT investments would unify processes, bypass bureaucracy, directly issue licenses and directly request funding from Greek banks. Through a unique funding route can achieve minimized costs and time to further support their production lines. All in the same platform that will accelerate the whole process save time, resources and money. Additionally, primary suppliers can be incorporated in this platform (acquiring a unique id) and directly support export companies and production lines with raw materials in a live-time process.
- Agriculture** Agriculture can potentially become a primary pillar for the future development of the Greek economy, specializing in Mediterranean food, in super-foods, and special flavors. Experience shows that ICT investments can accelerate production, speeding-up the introduction of new varieties, and increase the quality of the final products. This can be done through electronic means in order to control diseases, increase productivity of the soil by controlling through electronic sensors humidity, temperature, pH, and other crucial chemical factors, or simply by supervising the fields from air with the assistance of drones. Agricultural firms can collaborate with each other by founding common funds and corporate entities. Later on, these entities can request funding from banks and investors to realize the insertion of technology in production of specific products that have a comparative advantage at a European level. Through economies of scale, can fund their projects with reduced interest rate, increase European market share and increase their total exports activity.
- Tourism** Greece is among the top international destinations with around 33 million arrivals and 17 billion euros income in 2018. This sector has clearly a comparative advantage at a global level. Apart from massive quantities and well known global destinations (i.e., Mykonos, Rhodes, Chalkidiki, Crete, Corfu, etc.), Greece with the assistance of ICT investments will have the ability to focus on boutique, specialized tourism products. This can potentially include geographical areas of unique interest such as lakes, rivers, mountains and cities with archaeological sites or (and most importantly) thematic areas such as conference tourism, religious tourism, food/wine tourism, museum tourism, tourism for people interested in byzantine culture, “philosophy tourism” (i.e., tourism targeting people with deep appreciation for ancient Greek philosophy and culture), and other areas of high interest that Greece can potentially support their development. With the assistance of ICT technologies, a new platform can be created interconnecting boutique hotels and other tourism infrastructure with such niche areas. Through this platform, a new international client will have the ability to view the thematic areas (with the support of videos and other informational material), choose the product and directly make the reservation with the interconnected boutique hotels/resorts. Over the last years, Greece has indeed an upward trend regarding the incoming tourists. What further needed is to focus on this specializing tourism that will add value in economy, create new jobs, and accelerate further economic development.
- Renewable energy** Renewable energy is another field that Greece can further enforce one of its comparative advantages. By exploiting the so called “Greek sun,” the winds of the Aegean, and the current hydroelectric infrastructure, which potentially can be further expanded, Greece has the ability to massively increase its produced energy from renewable resources and covering not only

its needs but also making exports to neighbor countries. Regarding the EU 2020 target (energy consumption from renewable resources), Greece is on track. With the assistance of ICT investments and through electronic platforms, the country can make clever allocations of the produced energy coming from renewable resources. In this way, the country can save money and resources which at a later stage can be re-routed back to the system or moving towards industry and export companies reducing their cost and further increase their productivity and income coming from exports. Most people of Greece are primarily living in two cities: Athens and Thessaloniki. In fact, 70% of Greek people live in the metropolitan areas of these two cities. This fact, in terms of energy consumption, can facilitate the clever energy allocation which with the assistance of ICT investments can potentially lead to economies of scale and the acquiring of benefits mentioned before.

- **Education** Education can potentially become another factor of success for the future economic development of the Greek economy. In this field, Greece can exploit its position in the Balkan Peninsula and its European experience and link this with the European prospects of its neighbors. Right now, many public universities and private colleges have the ability for extroversion and international collaborations. Having already set up international partnerships (especially the private colleges) with British universities and other international academic institutions, Greek private education providers can further expand their activities to Balkan countries by providing distant educational services with the use of ICTs. Electronic platforms for asynchronous or synchronous education can be a fundamental part of this international education dimension. Such products can be directed to individuals, firms that wish to educate their personnel and other private and public entities. This service can add a tremendous and multiplying value in the Greek economy by attracting international distant students and researchers for university and professional education in various fields.

FUTURE RESEARCH DIRECTIONS

We have outlined how ICT investments can foster the Greek economy and for that matter the economy of any country that has similar characteristics with Greece. Once you have a vibrant economy, in which companies strongly use ICT technologies in their business, then one can expect to see new software and hardware companies to flourish. This will further allow companies to create new tools and utilities. In addition, Greek Information Science departments can be associated with such companies preparing their students for their professional life. This of course will have a tremendous multiplying effect in the country and it will stop the brain-drain that happens right now. One can further investigate in full detail all these prospects and abilities.

CONCLUSION

In this chapter we discussed how ICT investments can foster the troubled economy of a country. In particular, we used Greece as a test case to see how its economy can get the required stimulus to begin functioning and maintain a viable rate of economic development. We have examined various economic areas and how these areas can be further expanded with the use of ICT technologies through investments in crucial sectors that appear international comparative advantage. Naturally, there are many other sectors that can be included in such research and analysis.

KEY TERMS AND DEFINITIONS

Economic Crisis: A situation in which the economy of a country experiences a sudden downturn.

Economic Recovery: Is a period of increasing business activity signaling the end of a recession.

Economy: The large set of inter-related production and consumption activities that aid in determining how scarce resources are allocated.

ICT: Is an umbrella term that includes any communication device or application, computer and network hardware and software, satellite systems and so on.

Investment: Is an asset that is purchased with the hope that it will generate income or receive appreciation in the future.

Dimensions of the Digital Divide

Marcus Leaning

University of Winchester, UK

Udo Richard Averweg

eThekweni Municipality, South Africa

INTRODUCTION

The digital divide is a term used to describe a difference in the use of digital (including social) media between and within populations. It concerns the extent to which engagement with digital media causes and is caused by varying demographic factors. The term was first used in 1999 (van Dijk, 2017) though an understanding that a gulf between those able to use and access information through digital media and those who could not, existed since the mid-1990s. The issue received considerable attention in the early to mid-2000s (for example, by the Organization for Economic Cooperation and Development (OECD)) yet in contemporary times the term seems to have drifted out of the public consciousness. However, there are still large differentials between regions of the world in terms of rates of access to digital media. There are also notable differences between communities in developed countries in terms of what forms of access people have and what they are able to do with this access.

As understanding of the divide has progressed conceptualizing the various reasons people are not able to avail themselves of the potency of computers and the internet has become more sophisticated. In this article, the authors contend that the idea of the digital divide can be understood to operate in a range of different ‘dimensions’. Previous work on the topic has identified different historically situated ‘orders’ of the digital divide and in some ways the dimensions under consideration here match these. However, such accounts tend to locate the forms of divide as occurring sequentially and that the latest form of divide presents the most prescient problems. In contrast the authors contend that the differing forms are still present and that the problem is a multi-faceted one which requires a multi-level approach to address. In this chapter the authors consider the three main dimensions that impact upon a person’s ability to make use of digital media.

BACKGROUND

In its simplest terms the digital divide refers to a form of social stratification that is simultaneously enacted and furthered by an individual’s ability to utilize digital media to render their own self-interest (Leaning, 2017a). That is, our access to and use of digital media in part determines our social opportunities but is simultaneously related and determined by forms of social inequality (Ragnedda, & Mu, 2013). It impacts an individual’s ability to use digital media to assist them in their lives but also impacts upon their engagement with political processes. Accordingly, the digital divide is both a problem for individual people and also for the operation of democracy and citizenship.

In this article the authors first consider the physical (access to the equipment to connect) and material (ability to afford the expense of connection) digital divide and rates of access across and within a

DOI: 10.4018/978-1-7998-3479-3.ch115

number of countries. Second, the authors then look to the issues of training and education that impact upon people's ability to access computing technology. Third, the authors look at what people are actually doing online and will note that demographic differences between people are often also manifest in their forms of behavior and ability to leverage digital communications to their advantage.

The authors term these different barriers as different dimensions to highlight their interrelatedness and concurrency. It is felt that to refer to the problems as barriers or orders implies that the issues occur sequentially. While they were identified sequentially, treating them in this manner means that the complexity of the issues and the interrelatedness of the three issues may not be fully appreciated. Instead the authors refer to the issues as dimensions of a complex problem. The dimensions the authors identify here operate in concert and thus cannot be addressed in a piece-meal or singular fashion.

FOCUS OF THE ARTICLE

This article will look at different aspects of the digital divide. The article is structured so that the broad themes (different dimensions) cover the following aspects, as reflected in Figure 1:

- physical and material barriers;
- training and educational barriers; and
- participation divide issues and barriers.

Figure 1. Dimensions of the digital divide in contemporary society

The authors now explore and discuss these each of these different dimensions in the hope that readers may have their awareness and understanding of these digital divide topics strengthened.

Physical and Material Barriers

There are now high levels of access to the internet in most developed countries and indeed across other regions of the world. For example, in North America and the Caribbean the average access rate is 76.2%, in Europe it is 80.2%, in South America it is 65.3%, across Asia and the Middle East access is 47.0%, in Europe it is 80.2%, in Australia and Oceania it is 69.6%, while in Africa it is as low as 47.0% (Leaning, 2017b). There are, however, very significant disparities of access and many countries lag far behind the most connected regions: while Australia has nearly 85.0% of its population online, only 7.0% of Togo's population has the same access. It must be noted, however, that for many access to the internet comes not through a connected computer but through a mobile device with an internet subscription. Such practices further complicate the picture as in many parts of the world users may possess multiple subscriptions to take advantage of cheaper rates for certain actions.

Furthermore, within countries there are further divides, these replicate and indeed exacerbate other forms of social inequality. Forms of division such as gender (Cooper, 2006; DiMaggio, Hargittai, Neuman, & Robinson, 2001; Dixon, Correa, Straubhaar, Covarrubias, Graber, Spence, & Rojas, 2014), educational level (van Dijk, & Hacker, 2003), ethnicity and race (Hoffman, Novak, & Schlosser, 2001; Jackson, Zhao, Kolenic III, Fitzgerald, Harold, & Von Eye, 2008), language (Gurstein, 2003; Mallikarjun, 2004), social class and financial standing (Clayton, & Macdonald, 2013), age (Cresci, Yarandi, & Morrell, 2010), sub-national (Chen & Wellman, 2004) and intra-national regions (Vicente, & López, 2011) have been considered as being important in determining an individual's ability to access computers and internet technology. Such lack of access for members of these groups often results in inequality being further entrenched. Access to the internet is both restricted by various forms of social inequality but also exacerbates and contributes to such inequality as the possible benefits of digital media are denied.

Attempts to deal with these problems run into multiple difficulties. van Dijk's 2005 study determines that a user's motivation may prove to be a barrier that exists prior to access. Of those not online, a small percentage are in that position as they lack the motivation to be online – they are 'want nots' as opposed to 'have nots' and the reasons for not wishing to be online are complex. This may be because of a fear or anxiety, a lack of time, not seeing the value of access, fears over the effects of computing or simply a disinterest in computers. One needs to be cautious about saying such beliefs are problems, however, and there may be many legitimate reasons for not wanting to be online. Once the barrier of motivation is surpassed, the key barrier facing users has been understood to be one of access.

A number of academics (van Dijk, & van Deursen, 2014; Warschauer, 2004) have noted that the issue of access to computers and the internet forms is more complicated than the issue of having direct physical access. van Dijk (2005) and Dijk & van Deursen (2014) note access is comprised of two separate aspects: physical access – which consists of the direct contact with an internet enabled computer – and material access – the wealth to be able to afford the expenses of being online such as broadband subscriptions, costs of various services and 'apps' and subscriptions to services. If one considers the use of mobile devices in developing countries, a number of services also require the user to have credit cards and other financial tools to avail themselves of access - barriers that prevent those of limited wealth from engaging. While many may have physical access through using a computer, through work or in cybercafes or other locations or even possessing one material access proves a more difficult barrier to overcome as it is linked to financial inequality. Warschauer (2004) notes the complexity of successful computer usage "access to ICT is embedded in a complex array of factors encompassing physical, digital, human, and social resources and relationships".

During the late 1990s and much of the early 2000s the issue of the digital divide received attention at the highest of governmental, non-governmental, corporate and charitable levels (Klein, 2004) as well as extensive academic interest (Norris, 2001). Solving the problem of the digital divide became a significant area of domestic and international development activity and consumed large amounts of funding. Many of the solutions proffered involved the greater deployment of technology allowing individuals who were not connected the opportunity to become connected. While in developed countries the issues of physical and material access have been ameliorated to a large degree, they still present significant issues to people in the developing world and are a very current problem.

Training and Educational Barriers

Significant effort was put into addressing physical and material barriers during the early 2000s. Though there were a few instances, such as Costa Rica, where direct state investment was used successfully to provision digital service, in most cases the approach to provision has primarily been through the extension of commercial services be they commercial broadband or mobile services. However, it soon became evident that access alone was not the entire solution and the simplistic binary nature of the divide began to be questioned. This resulted in more sophisticated models being developed to account for the digital divide.

The new models conceptualized the digital divide not in binary terms but instead saw a spectrum of ability to access and use of networked computers (van Dijk, & Hacker, 2003; Warschauer, 2002, 2004). In such accounts, though access was still a barrier, other factors became increasingly recognized as preventing full engagement with digital media (Hargittai, 2002) and Warschauer's (2004) critique that access was part of a complex range of relationships and social factors was developed further by a number of authors. The most significant problem identified in these accounts was the lack of skills in using computers and internet technologies and this soon became the focus of attention in efforts to address the divide.

A number of new models of skilled usage were proposed to account for differences in participation (Barclay, & Duggan, 2008; van Dijk, 2005). These models determined a deficit in skills as being central to restricting people availing themselves of the benefits of digital media in terms of activities such as economic activity (König, Lorenz Graf-Vlachy, & Mammen, 2016), business (Arendt, 2008), health (Norman, & Skinner, 2006) and political engagement (Morris, & Morris, 2013).

Actual Skills Which Need To Be Improved

van Dijk (2005; van Dijk & van Deursen, 2014) advanced the approach further and prepared exhaustive methods for determining the actual skills that needed to be improved so that the divide could be addressed. van Dijk makes use of a model of capital - initially proposed in the work of French sociologist Pierre Bourdieu (Bourdieu argued that social inequality was not simply a matter of not having enough money. Rather he identified three forms of capital (financial, social and cultural) that facilitated social stratification. To these three, the Dutch critic Cees J Hamelink (2000) proposed that as the Information Age progresses, a fourth form of capital must be added, that of information skills as this assists a person's ability to progress in society).

van Dijk & van Deursen (2014) develop this approach and offer a six-part model of the skills required by individuals to bridge the divide. This model has proven significantly influential in developing numerous programs to equip students with the skills for using digital media in contemporary times and

it is worth considering the model in some detail. Van Dijk & van Deursen contend that users need two new sets of skills specific to the digital age:

- *operational skills* – the practical know how to engage with digital media; and
- *formal skills* – the technical practices for using hyper media.

Van Dijk then identifies four further content related skills:

- *information skills* – the basic skills of handling information;
- *communication skills* - being able to communicate on the internet;
- *creative skills* - for digital media content production; and
- *strategic skills* – to use one's creative and information skills in a useful manner.

However, while van Dijk & van Deursen's model presents a useful tool for evaluating and developing educational practices for addressing the second dimension of the digital divide he does not advance the nature of the critical approach to information that is developed. Though there is some very brief mention of evaluating information, the proposed model does not

- incorporate any real consideration of how texts themselves should be considered;
- consider the ways in which information that is mediated through a variety of sources and often relayed through different social media lens and channels; and
- explore how a user's data is used by social media platforms and other organisations.

Thus the skills identified by van Dijk & van Deursen and incorporated into many models, also need development and updating to address more recent activities such as the use of individuals social media data profiles. One potential option to address this is the development of a new set of competencies broadly referred to as Media and Information literacy. This literacy incorporates a more critical aspect and utilizes some of the critical methods that have been present in media education for some years but not previously applied to information resources.

A further concern with the information-intensive model developed by van Dijk is that while some attention is paid to the creation of digital media content in the model, this is rather limited in its understanding of the nature of participatory culture and the differing levels of engagement with digital media by different communities.

Participation Divide Issues and Barriers

The development of extensive forms of training provision and skilling practices is understood to have addressed the problems identified in the second dimension of the digital divide. Computing and information skills became an accepted part of the educational curricula for students of all ages in many countries. Moreover, the growing acceptance that people regularly need to update their skills in the workplace and the emergence of the idea of lifelong learning resulted in numerous courses for adults outside of traditional educational spaces. Libraries and similar venues became recognized as places to equip people with the necessary skills to use digital media.

Alongside these changes in how education was understood, during the mid-2000s there was also a range of technological developments (such as the development and proliferation of mobile devices and

the emergence of web 2.0 and social media platforms). There were also other developments and systems which afforded users a greater opportunity to produce and disseminate their own content.

The ability to perform such actions was investigated by academic researchers with one branch of research considering the demographic characteristics of those who were producing and sharing material. This area was expressly concerned with the issue of whether (if access and training were equal) an individual's propensity to engage in the productive aspects of social media is adversely affected by 'real world' material, cultural and non-technical educational advantages – are extant inequalities reduced or exacerbated by an individual's ability to participate? This approach was specifically concerned with whether social inequality can be addressed and reduced through digital media, whether social media simply reflects extant social inequalities or whether media further worsens existing problems.

However, establishing a direct link between markers of social inequality and a propensity to engage with social media and participatory culture is difficult. Micheli (2015) finds no correlation between the parental employment status of users and their proclivity to engage with social media. However, a link is noted between particular activities – such as information seeking - which contributes to the building of social capital and the parental social class. Moreover, engaging in social media is a varied activity ranging from a largely consumptive activity through to a highly productive one in which users create content – social media can be and is put to many different uses in people's lives (Lutz, & Hoffmann, 2014). Furthermore, Blank (2013) and Blank & Reisdorf (2012) note that content production is not a single activity but incorporates many different practices, ranging from posts on social networks, creating written texts, static and video texts, acts of citizen journalism and editing, and repurposing other's content.

The relationship of social inequality and the propensity to participate is complex. Once issues of access and training are addressed, a user's direct ability to use social media and the amount of use of social media usage does not seem affected by the status or forms of social disadvantage their users endure. Indeed, in some instances those from disadvantaged backgrounds have a greater degree of participation than those from a non-disadvantaged social milieu. Blank (2013) and Hoffmann, Lutz & Meckel (2015) both noted that a larger proportion of time is spent on social media by those from low socio-economic backgrounds than those from more wealthier groups. However, what forms of social media are engaged in do seem differentiated by levels of educational attainment and parental social class (in the case of younger users).

Brake (2014), in drawing upon a data set from Oxford University and using a broad range of literature, notes how activities of a more creative nature such as blogging, creating content on Wikipedia or forms of citizen journalism are activities engaged in more by those of higher economic status than those of a lower one. Similarly Hargittai & Jennrich (2016) and Hargittai & Walejko (2016) note how socio-economic status is linked to the production of creative content. Correa (2016) notes no difference in the amount of social media use between members with different educational levels when the use is for social purposes but does identify a difference between users when the task is searching for information. Thus it appears there are particular productive activities that are performed more by people of a higher socio-economic group than those from lower socio-economic groups.

While certain proponents of digital and participatory culture contend that use of any social media builds communication skills and confidence (Jenkins, 2006), it appears there are distinct activities that seem to be performed by particular groups. Some of these activities, such as searching for information, using social media for instrumentally career-focused networking and building personal brands, are correlated with users of higher economic standing and other forms of privilege. However, it is difficult to determine the direction of travel – do socially advantaged groups use social media because they are advantaged or are they advantaged because they use social media in this way? A number of studies (see,

for example, Radovanović Hogan, & Lalić, 2015) indicate that the social status impacts upon the way in which social media is used. The determination of which social media practices a user engages with appeal is, to a degree, determined by the level of social advantage a person has. Social media usage is a consequence of prior existing social factors rather than a mitigating factor to them.

SOLUTIONS AND RECOMMENDATIONS

The various dimensions of the digital divide pose a challenging problem. Initial efforts were made to alleviate the disadvantages faced by certain groups and populations which would exclude them from obtaining the advantages of access to digital media. The recognition that education and training were a further requirement to address the issue added a further aspect to the problem and also refocused efforts away from the physical and material problems onto human and social factors. The targeted educational practices of the various digital literacy programmes developed to address the skills divides are still very current issues.

A raft of new initiatives are being developed by international agencies (such as UNESCO) to broaden the training beyond the primarily technical and instructive methods into more nuanced, critical and sophisticated approaches. These new approaches seek to expand training beyond the ideas of how to use communicative technology into challenging the problems of 'Fake News' and propaganda.

The growth of social media also posed questions about how socially disadvantaged groups used different forms of social media and engaged in different practices. This aspect of the digital divide is significantly problematic as research seems to indicate that the expansion of the popularity of social media has resulted in it actually becoming a new space in which extant disadvantage can be enacted. Accordingly, the provision of access to and skilled use of digital media technology and social media may not be a means to alleviate social disadvantage but a new channel by which such disadvantage is continued.

The provision of services, delivery of training and even developing the adoption of specific practices may have side-effects to the intended alleviation of disadvantage and instead social media becomes a further arena through which social inequality is enacted. The provision of such technology should not be seen as a means to alleviate inequality but may indeed be a new means by which such inequality is enacted, facilitated and accelerated (Leaning, 2009).

Accordingly, how one understands the digital divide may be understood not as one of multiple barriers to overcome but rather as one of a social problem of which there are multiple dimensions.

FUTURE RESEARCH DIRECTIONS

To advance understanding of the digital divide, the authors advocate that future research be directed towards a greater understanding of how existing social disadvantages are enacted through social media - explicitly through the differences in use by differing populations and how certain practices can assist in ameliorating social disadvantage. Such digital divide research should dovetail with the approaches currently undertaken in OECD countries – see www.oecd-ilibrary.org

CONCLUSION

The three main dimensions that the digital divide can be understood to operate in were articulated so that the associated prescient problems may soon gain resolution. The authors have shown that in contemporary society the digital divide is a multi-faceted problem which requires a multi-level approach to address the dimensional issues raised.

KEY TERMS AND DEFINITIONS

1st Dimension Divides: The physical and material barriers to participation.

2nd Dimension Barriers: The educational and training barriers to participation.

3rd Dimension Barriers: The differences in levels of participation.

Critical Information Literacy: The higher-level skills and understanding that result in a person being able to make use of digital media to further their own interests.

Digital Participation: The idea that full engagement with digital opportunities assists in furthering one's self interest.

Information and Information Literacy: The skills needed to successfully use computing technology.

Social Stratification: The way in which a society is organized so that opportunities and benefits are more available to certain members of a society than others.

Importance of Digital Literacy and Hindrance Brought About by Digital Divide

INTRODUCTION

In this century we have seen rapid advancements in technology, and more innovative devices spawn every year. For better or for worse, technology have changed the way people go about their everyday lives. Humanity have achieved technological feats that were previously thought impossible such as computer processing and online communication. Along the way, a technological paradigm has emerged that has further altered the way people live; digital technology. Digital technology includes all types of devices and electronic applications that use and store information in the form of binary code, and these information can usually be altered by capable devices such as desktops, laptops, tablets and smartphones. Presently, information is available in vast amounts on a global computer network called the Internet. One cannot simply utilise technology, it requires a certain degree of skills and competencies. These skills and competences are commonly known as *digital literacy*. Digital literacy showcases an individual's grammar, vocabulary, writing, and typing skills on various platforms, and the appearance of the Internet means that digital literacy also extends to the capability of individuals in extracting and critically analysing information on the Internet and social media. With these advancements in the field of technology, it is vital to understand the importance of digital literacy.

People who possess sufficient amount of digital literacy will be able to reap the benefits of digital technology and will have their lives continuously improved. However, not everyone experiences the same benefits. A global phenomenon called digital divide has recently appeared, whereby there exists a gap between those who have access to technology and those without. Across the globe, Internet technology has developed unevenly throughout. Countries who have access to the Internet are able to develop, while countries who have no means of access or limited access to technology and the Internet are left behind socially and economically, and remains poor.

Thus, it is the objective of this article to provide a clear and concise definition of digital literacy. While many studies have explained in detail the definition of digital literacy, this chapter would like to complement that definition by applying it in the context of an Input-Process-Output (IPO) model, in order to provide more clarification and to help the general public better understand the concept of digital literacy. The article would then prioritise its objective to justify why having a certain degree of literacy is important from different industries. The importance of digital literacy is even more pronounced with the rapid rise in the usage of Internet (Internet World Stats, 2018, Dec 31). However, digital divide has plagued the world since the Internet first came into existence. Due to the negative social and economic

DOI: 10.4018/978-1-7998-3479-3.ch116

implications of digital divide, the article would then suggest solutions and recommendations on ways to tackle digital divide.

BACKGROUND

The word *digital literacy* and the topic surrounding it is relatively new, going back only as far as the late 1990s (Lanham, 1997; Pool, 1997). Interestingly, digital literacy existed years after the Internet first made its appearance in 1991 (Berners-Lee, Cailliau, Groff & Pollermann, 1992). Since then, one of the earliest literature introducing digital literacy is done by Gilster (1997), in which he provided the explanation for the definition of digital literacy as possessing the ability to process information via technological means. However, the broad nature of this definition may have caused more questions than answers. The preceding literature that follows have attempted to interpret, analyse and evaluate this definition (Bawden, 2001; Robinson & Bawden, 2001, June; Williams, 2006). Bawden (2008) explained Gilster's definition further by applying it in the context of the present time; the digital age. The Input-Process-Output (IPO) model was first used to evaluate training (Bushnell, 1990), and has since been used in literature to describe a particular programming process (Curry, Flett & Hollingsworth, 2006; Grady, 1995; Goel, 2010; Zelle, 2004), but none have covered in the context of digital literacy.

Digital literacy is not to be confused with other similar literacies (Koltay, 2011) such as computer literacy (Hoffman & Blake, 2003), media literacy (Livingstone, 2004), and information literacy (Bruce, 1999), whose words have existed long before the emergence of digital literacy (Bawden, 2001). The existence of these words is in line with technological advancement; the more technology advances, more literacies begun to appear. Albeit the literacies are used interchangeably, ultimately they possess slightly different meaning from one another.

With technology progressing at a rapid pace, more studies have begun to appear in order to examine the underlying meaning behind digital literacy (Buckingham, 2008; Martin, 2008). Digital literacy requires skills and training to be able to competently process and produce information on digital media, which is far more easier for younger generations to master as compared to senior generations. In today's digital age, technology have made lives more convenient and as a result, people have started to rely on technology and are dependent on it to get things done. These studies culminated in the realisation on the importance of having a certain degree of digital literacy in order to survive today's digital age (Eshet, 2004; Martin, 2005).

Apart from digital literacy, digital divide is also an area that only been recently explored (Hoffman & Novak, 1998; Sidney Howland, 1998). Recent researches on digital divide include the study of the causes of digital divide in different context such as in tourism industry (Minghetti & Buhalis, 2010), as well as the context of a group of countries such as European (Union Cruz-Jesus, Oliveira & Bacao, 2012). In fact, the usage of the word digital divide coincides not long after literatures in digital literacy have begun to appear (Jaeger, Bertot, Thompson, Katz & DeCoster, 2012; Warschauer, 2002). As a result, there are currently only a few studies that determines how to solve digital divide (Ali, 2011; Lopez, Gonzalez-Barrera, & Patten, 2013).

FOCUS OF THE ARTICLE

Definition of Digital Literacy

This paper would define the concept of digital literacy as the skills, abilities and competence of each human individual in using technology or any electronic devices with Information, Communication and Technology (ICT) capability (Buckingham, 2010), in order to discover, assess and create information by way of virtual or digital means (Buckingham, 2015). This means that, an individual must possess a certain degree of knowledge and mastery in ICT to properly use that information. Individuals who are digitally literate would then be able to use the information appropriate to their needs by constructing and interpreting meaning in the form of texts, sounds and images.

Deriving from the widely used model to describe how a typical information processing system operates (Bushnell, 1990; Rabitz, Aliş, Shorter & Shim, 1999), this paper seeks to adapt the Input-Process-Output model (IPO) model in the context of Digital Literacy. Because Digital Literacy involves the use of similar information processing system to generate the required output, it is possible to adapt the model in the context of digital literacy as the IPO model embodies how the inputs are received from a source, whereby the inputs are processed by the processing system, which produces outputs in the form of results. In the study of Computer Science, the process is highly similar to a computation of mathematical expressions, whereby a computer system is used to equate raw mathematical objects into useful mathematical expressions (Al-Rfou, Alain, Almahairi, Angermueller, Bahdanau, Ballas, & Bengio, 2016). The nature of Digital Literacy involves the transition and transformation of information while the IPO model serves as a program that can showcase and embody how that information are undergoing the transformation. The IPO model seeks to specifically identify the items in question for input, process and output.

Figure 1. Input-Process-Output (IPO) Model in the concept of Digital Literacy

To further apprehend the underlying meaning behind digital literacy, it is important to further understand the Input-Process-Output (IPO) model (Ilgen, Hollenbeck, Johnson & Jundt, 2005) with the use of examples. The IPO model forms the basis of many frameworks including digital literacy. From the IPO model of Figure 1, skills and competences of users are considered the input. Input also includes the critical thinking skills of users, in which how capable they are in making evaluation and critical judge-

ments with the information in hand. Pre-determined information from sources such as the Internet and social media also serves as input.

At the next stage, process takes into account software and programs in computers that are being used to create and process new information. Commonly-used applications such as word processor programs, spreadsheet programs, presentation programs, and database management system are some examples. These programs simply enable the altering of information, and made the task of altering information easier. However, how the information is altered depends on the skills of users.

The model then produces output in the form of processed information. This new information created by the application in the process stage can also be synthesised with the aforementioned pre-determined information from the input process. Processed information must be as clear as possible in order to be understood by the majority of people. Output also occurs in the form of contextualized information called knowledge. While information is raw data converted into a meaningful context, knowledge is insights and understanding that would benefit an individual (Kanehisa et al., 2013).

Digital literacy is not to be confused with the general definition of technology itself. Technology include crude and physical tools that makes tasks easier, and these tools may have no digital features whatsoever. The more accurate term for technology associated with digital literacy is digital technology. While digital literacy initially focuses on digital skills and stand-alone computers, it has since shifted to network computers such as the Internet and social media.

Importance of Digital Literacy

For this subheading, the significance of possessing adequate digital literacy would be discussed from the various sectors in a typical economy, as this chapter argues for a push towards digital literacy among the populace across the globe. This includes broader perspectives such as the public sector and the simple necessity to survive in today's digital economy, down to more specific point of views which include Classroom Education, Retailing and Healthcare. In some case, current examples would be made in each instance as well as references to IPO model in the various sectors.

To Survive Today's Digital Society, and Foster Autonomy Rather Than Dependence

Digital literacy must no longer be seen as an option for individuals, but rather a necessary aspect in daily lives. Throughout the world in the 21st century, almost every aspect runs on digital technology. Consider, the smartphones are used for simple communication and social networking activity, while computers are being used as a platform for web-browsing, to advanced video, audio and image programming. Technology has become a permanent fixture in our lives. With example from the IPO model, individuals must have the ability to comprehend and evaluate instructions in the form of texts on graphical user interfaces, and then create meaningful context out of it (Eshet, 2004). However, there is often the issue of ethics in digital context such as copying other people's work on the Internet, as well using the information displayed to create something that is deemed morally wrong (Capurro, 2009). Thus, it is vital that a boundary be established for individuals to differentiate between right and wrong in the form of digital legislations. For instance, due to China having one of the highest number of Internet users in the world, China has implemented digital legislations in order to reduce the rate of cybercrimes (Qi, Wang, & Xu, 2009).

The consequence is that society have begun to be dependent on technology and thus, cannot live without it. This results in the notion that we are living in an age of digital, rightly called *digital society* (Martin, 2008). How would an individual expect to survive in the digital society if they do not have a single clue on how to utilise digital technology, when the completion of their tasks hinges on it. Thus, in order to adapt to this technological paradigm, it is essential that each and every individual be digitally literate to survive. However, there must be an establishment between the boundary of dependence and autonomy. With digital literacy, an individual can properly learn that digital technology are not to be dependent on completely, rather it is something that can support an individual be more autonomous and self-independent in order to better themselves in terms of surviving in today's society (Kipnis, 2012).

Classroom Education

Digital literacy is of the utmost importance in the realm of education. Traditionally, teachers use whiteboards and chalkboards to explain a subject matter, and print exercises in the form of hardcopy for students to complete. These crude methods however are slowly becoming obsolete, as students are accustomed to using their smart devices in class. Fortunately, digitally literate teachers and students can take advantage of the conveniences of these digital technology (Rhodes & Robnolt, 2009). Students can showcase their learning by understanding how to use Internet features such as search engines, web browsers, blogs and emails. Teachers and students are able to create online content to be utilised both in and out of the classroom, without having to wait for the next class. These online contents tend to include texts, images, sounds, videos, and animation, which makes learning more engaging. In class, a new interactive whiteboard can be used on a daily basis. Without digital literacy, teachers and students are not able to take advantage of digital medium. The term for this resourcefulness is E-Learning (Driscoll, 2002).

Outside the classroom, students are often left to their own devices to do their homework, and in some cases, have no means to contact their teachers. Any enquiry has to be made in the next class, and timetables are often so fixed that they are often not flexible enough to change according to students' availability. Whereas in the old days teachers could only get in touch with students in class, teachers can now connect with their students via social media. Smartphones have enabled teachers to track the progress of students and update them of any changes in timetable, while enquiry only requires a few button pushes for students. Outside of education, it is a means for teachers to observe the activities of their students. Thus, digital literacy has enabled a two-way interaction between students and teachers, which greatly enhances the learning experience, as compared to the one-dimensional nature of previous ways (Hague & Payton, 2011).

From an IPO model perspective, Digital literacy in education is more than being able to find information. It involves students being able to critically evaluate and make judgements on information, and if possible, improve upon that information. Students are able to evaluate the trustworthiness and accuracy of information found on the Internet. Thus, not only does it teach students on how to improve their thinking skills, but also help improve the work of others, and thus, benefiting everyone in society. It can be argued that digital literacy is even more important and needs to be more prevalent in Higher Education, whereby it is at this point where students would often need to equip themselves with a high level of digital literacies and competences before going out into the ever-changing and dynamic labour market that is slowly utilising the latest technology (Santos & Serpa, 2017; Shopova, 2014). In particular, the teaching and learning of Science curriculum is cited as one of the curriculums where digital literacy needs to be emphasised on (Ng, 2012).

Online Shopping and Corporate Settings

Retail outlets are under threat from a new method of shopping; online shopping. There are two ways for businesses to commercialise their products, via retail outlets, which requires a physical shop for one-on-one interaction, and online shopping, in which products are sold online on websites, which is commonly known as E-Commerce (Turban, King, Lee & Viehland, 2002). The difference is that unlike retail outlets, online shopping normally requires a degree of digital literacy for transactions to occur between buyer and seller. Due to retail shopping requiring physical stores, they are limited to the local area in which they are operated in, potentially limiting the number of consumers. With online shopping, products can be sold to consumers regardless of their geographical location. Digital literacy allows online seller to design and customise their own website interface. Consumers, at a push of a button at home, could browse for the goods on the Internet and make purchases, and businesses do not need to waste precious resources on setting up shops. Thus, with digital literacy, transaction is made faster and more cost-saving than ever before. The rise of online shopping only serves to highlight the increasing importance of digital literacy in shopping context (Scott, 2001).

In corporate (enterprise) multinational settings, communication has always been an issue due to the relatively large size of the organisation. This diseconomy of scale is made worse with the difference in language in foreign branches (Canback, Samouel, & Price, 2006). However, this barrier to communication can be overcome by using translation software. These advanced software are capable of translating foreign languages for everyone to understand while giving employees the platform to learn and speak new languages, further reducing the barrier to communication. However, these software require organisations to be digitally literate, and it is vital for organisations to ensure that their own employees are digitally literate by providing the necessary education and training. In terms of management, the capability of software to send messages swiftly and to convene low-cost video conferences has enabled organisations to easily keep track of their branches remotely.

Task-wise with the application of an IPO model, digital literacy has made the production and marketing of products easier. After inputting raw materials and components, products can be designed beforehand by using computer-aided design software, and in advertisements, video editing has made it possible to rearrange video shots to create advertisements to be displayed virtually on the Internet. These tasks normally require an insurmountable amount of efforts, but thanks to computers, they can be done in a short amount of time, effectively increasing the production output of goods and services. Suffice it to say, digital literacy results in increased labour productivity among employees. In today's digital society, gone are the days when job candidates are only encouraged to list information technology (IT) skills such as being proficient in PowerPoint on their resume, when such skills are now considered standard.

Healthcare

Digital literacy has always been a crucial part in healthcare for nurses as well as patients. The traditional paper health records have been replaced to give way for electronic means. This is widely known as e-Health (Oh, Rizo, Enkin & Jadad, 2005). With health records being able to be processed at a click of button, it is now more convenient and less time-consuming to look through a patient's health record. This, however, requires nurses being trained in the use of technology. From an IPO standpoint, Digital literacy is needed for nurses to update a patient's health record by inputting crucial patient data such as medical conditions, weight, age, medical test results, and vital signs. Nurses are then able to process this information in order to administer and prescribe medicines as outputs perfectly suited for each patient

depending on sickness and allergies of patients. There is an increasing trend of transforming traditional healthcare to digital health, which refers to the utilisation of technology in order to increase the rate of healthcare delivery (Meskó, Drobni, Béneyi, Gergely & Gyórfy, 2017).

In healthcare, applications are often used in smartphones. In the event of booking for an appointment, digitally literate patients could simply connect to the Internet in their mobile applications to do so. These applications can assist them manage their health by tracking their daily calorie intake, heart rates, intensity of exercises done per week, diabetes level and blood pressure as well as weight loss or gain. Applications are also means for hospitals to raise health and medical awareness by providing online consultation and forums, giving advices on how to stay healthy and stressing the dangers of tobacco and other unhealthy products. Continuous technological developments in healthcare have saved countless lives and improved the quality of life even more. Health-care services need to maximise the training of nurses in digital literacy to enhance patient care.

Government

The centralisation nature of the public sector means that there are often many procedures and ‘red tapes’ which can cause process to take a long time. This involves numerous paperwork which also needs to be approved from the lower level to the higher level. Even with the help of electronic means, these processes can still be time-consuming, albeit faster than before. The embedding of digital literacy onto the public sector workforce is vital for a more faster and efficient public service delivery (Marchionini, Samet, & Brandt, 2003).

Digital literacy is very important as there is an increasing trend towards a digitised government called e-Government (Almarabeh & AbuAli, 2010). While privatisation is rapidly increasing across the globe (Allen, Qian & Qian, 2005), some services continue to serve under government control such as provision of water, police force, national defense and immigration. Common examples of public services include renewal of identification card, passport and driving licence, application for extract from criminal register or commercial register, as well as the forms required for starting a business. All of these processes require public sector employees to have a certain amount of digital literacy. These services are often displayed in government websites, and these websites must be maintained and kept up to date by employees who are digitally literate. Above all, from the viewpoint of an IPO model, digital literacy can help increase the rate of civic participation that enables people to voice their opinions. The technology in hand will allow a faster delivery of messages, whereby the government can give due feedback thanks to a two-way communication in technology which will further revolutionise democratic practices (Robertson & Vatrappu, 2010).

Hindrance of Digital Divide

For this subheading, the paper would be looking at the negative social and economic consequences brought about by digital divide from the perspectives of individuals, firms and governments. Digital divide is referred to as the gap in usage of technology, which could either be demographics or geographic in nature (Chen & Wellman, 2004). Digital divide is a worldwide phenomenon that plagues almost every country. It is more pronounced in countries that adopts a market economy, where the economy is influenced by fluctuation in prices, supply and demand (Moroney & Lovell, 1997), leading to unequal distribution of income and wealth among the populace, which in turn, leads to the classification of rich and poor people.

Although the number of people with access to computers and the Internet continues to soar across the globe, the digital divide also continues to grow at an alarming rate (Chen & Wellman, 2004). It is important to note that some people lack the means and understanding to utilise the technology in hand due to insufficient digital literacy. Despite the best attempts of governments in investing huge sums into technology and Internet infrastructure, the populace has no clue as to how to properly utilise this technology, and the vicious cycle continues in which economic and social progress is halted (Hargittai, 2001).

Economic Implications

One of the biggest issues associated with digital divide is the uneven access to technology. This is due to the costs associated with implementing a whole technological infrastructure. Countries with a healthy gross-domestic product each year would be able to slowly invest in this infrastructure for public consumption. However, for those without the means, will suffer the economic consequences of not being able to do so. A country's access to technological advancements is noted to directly correlate with an economy's development (Borensztein, De Gregorio & Lee, 1998), and vice versa.

Unfortunately, even after government spending huge sums of investments in technology, not all people have the technical know-how on how to utilise technology. This brought about the need to educate the populace in digital literacy which increases costs further in addition to costs of investment and implementation of infrastructure. Lack of IT skills would force them to shun the newly-bought technology giving rise to storage costs. Furthermore, with every update to technology, the cost is not getting cheaper. Thus, under-developed countries would be left behind due to a lack of funds to bridge the digital gap. Worse, they had needlessly spent the money on technological resources that are not being used, making them poorer.

Organisation-wise, redundancy happens due to digital divide. Some organisations are forced to dismiss employees who lack IT skills in order to make way for new employees who are digitally literate. This leads to the rise of ethical and trade union issues, due to workers being unfairly dismissed, and this may lead to lawsuit against the organisation. Costs would also increase should organisations decide to hire lawyers.

In households, it is found that Internet speed varies across regions in the world (Chaudhuri, Flamm & Horrigan, 2005). Internet speed is important as it determines how fast information could be received and delivered. Varying Internet speed results in social inequality whereby there are differences in income and social status. This in turn results in a distinct lack of social capital, whereby members in a society are not able to function as one (Hargittai, 2008; Witte & Mannon, 2010).

Social Costs

A country's social costs may rise when the poor began to resent the rich, especially in countries with a relatively high power-distance index (Hofstede, 2011). The desire to reap the same benefits of technology as those who can afford it have made the poor resorting to theft in order to access this technology either by force or otherwise. This can lead to thousands of dollars' worth of damage to personal property, harm to other individuals and criminal punishment for those who are caught stealing. As the poor people are forced to endure with a meagre amount of income, they are forced to resort to violence and crime just to survive.

For students at school, the inability to connect to the Internet has greatly hindered their ability to finish their homework, as they have no means of external support for knowledge. In extreme cases, especially

among poorer families, students do not even have access to computers, preventing them from doing digital exercises. This potentially leads to students receiving lower grades than their richer counterpart.

For individuals who have access but lack the proper skills, they would be the victims of cyber-bullying. Due to lack of digital literacy and knowledge of cyber-bullying, they are prone to cyber-bullying such as threats and intimidation, harassment, false gossip and rumors and being ridiculed on social media. They would have no means of defending themselves and cyber-bullying has more detrimental effects on younger generation, which may lead to attempted suicides (Qi, Wang, & Xu, 2009).

SOLUTIONS AND RECOMMENDATIONS

The next section will discuss in detail the possible solutions and recommendations on how to bridge the demographic and geographical gap that exists due to digital divide.

One of the methods to bridge digital divide is by educating the public on the use of technology. Digital divide is also caused by the population lacking in digital literacy despite having access to technology. Thus, to ensure that government investments in technology does not go to waste, it is imperative that the populace across the globe be educated on the use of technology. Although IT classes are the norm, it must be made compulsory in all curriculum from preschool to university level. This is important as it also fosters an atmosphere of technological acceptance. This improved rate of digital literacy will ensure that the technological resources that are readily available are used most efficiently to produce output. In order to encourage public acceptance of technology in general, this paper recommend the application of the widely-used Technology Acceptance Model (Chuttur, 2009) Based on this model, the public will be more accepting towards technology should they perceive that the technology in question is useful and easy-to-use.

In order to expose children in poor families to digital literacy, it is recommended that loans for electronic devices are to be offered. The purpose of this is to expose the populace from an early age to learning technology. Another alternative to loans is the offering of affordable laptops to children, akin to the one laptop per child initiative (Kraemer, Dedrick & Sharma, 2009). This is done by selling low-cost laptops that have the basic features that a child needs to learn digital technology. Unfortunately, not all countries can provide Internet access to its population due to the cost requirement. In this case, this paper recommends that instead of a whole area, only the poorest of remote areas be given relatively cheap Internet access. One such initiative was done by Free Basics (Sen, Pirzada, Phokeer, Farooq, Sengupta, Choffnes & Gummadi, 2016, November), brought about by a synthesis of corporations, albeit this time all services must be made available. It is urged that the private sector does a similar initiative in order to bridge the information gap in poor areas. In addition, to prevent the misuse of any information, the implementation of digital legislations would serve as rules and regulations for children to adhere to regarding the use of information (Qi, Wang, & Xu, 2009), which can potentially help reduce cybercrime.

For countries where there are resistances to adopting new technologies, fostering the right atmosphere is crucial. When possible, awareness campaigns must be initiated to influence a change in mindset. The public must be exposed on the importance of digital literacy especially among the senior citizens. Albeit this method sounds simple, it is by no means easy to implement as it involves conjuring multiple campaigns which can be costly. Public libraries must also be built in countries where digital divide is high. For people who cannot afford technology, public libraries are a means of last resort as a source of information (Kinney, 2010). The facilities in public libraries can also provide free training courses in order to educate the populace to be digitally literate.

However, the settings of these public libraries may not be enough to reach the populace, which will still result in prevailing digital divide. Thus, an initiative must be taken to ensure that automation is implemented in libraries (Mutula, 2005). With an automated system in libraries, not only the usual procedures of library cataloging and lending be more efficient, but ensure faster transition of information to the public, bridging digital divide.

Figure 2. Unequal Distribution of Wealth across the Globe (Source: World Inequality Report, 2018)

Finally, this article would like to implore wealthy organisations to devote themselves to charitable causes. Figure 2 shows that the richest 1% is twice as wealthy as the poorest 50%. As mentioned above, the nature of capitalism means that income and wealth will always be distributed unequally. It is forecasted that this inequality gap will worsen and widen, and if no action is taken, the poor will never be able to break their vicious cycle of poverty, leading to increased crime rate. The unequal wealth distribution means that the rich will always have more than adequate wealth to survive while the poor are scraping by with just a meagre amount of wealth.

Calls for multibillion dollar organisations to submit to charity must be initiated. The giving pledge is a prime example of a campaign to encourage such organisations to contribute a majority of their wealth for philanthropic causes (Chuang, 2015). The kindness to philanthropic causes will not go unrewarded especially if news of this spread throughout the Internet, as image and reputation will be enhanced greatly, to the point where there will be a build-up of followers and consumers, potentially increasing long-term sales (Porter & Kramer, 2002). These organisations are often seen as a bastion of selflessness and role models, potentially causing other organisations to follow suit.

FUTURE RESEARCH DIRECTIONS

Despite the topic revolving digital literacy is still at its infancy, one can notice an emerging trend toward digital literacy as more literature emerges. This highlights the potential of this topic, and this article paves the way for future researchers to delve deep into the importance of digital literacy in more various sectors. More studies needed on the application of the IPO model as the IPO model can be applied to many different scenarios that involves input, process and output. The study of other types of literacy that are similar to digital literacy such as information literacy, media literacy and computer literacy could also be pursued by future researchers. Future researchers could also add on and provide solutions and recommendations from more different perspectives on how to solve digital divide. Above all, a research into unequal wealth distribution that is causing global digital divide would be very useful.

CONCLUSION

In conclusion, the article has provided a definition for digital literacy, in the application of an IPO model, although the concept itself remains unchanged from other definitions of digital literacy in literature. The article also provided a brief overview of having digital literacy in different sectors or industries. e-Learning, e-Commerce, e-Health and e-Government are rising in importance, highlighting the notion that the population needs to have a degree of digital literacy. For a country to achieve economic and social prosperity, its population need to be digitally literate to utilise its technological resources, as humanity is currently living in the digital society, where people are heavily-reliant on digital technology. A lack of digital literacy, as well as the uneven access to technology is the cause of digital divide. Digital divide has detrimental effects, especially to an underdeveloped country, and everyone from governments and organisations down to individuals play an important role in solving digital divide. The solutions and recommendations provided above serve as a general guideline on how to solve the issue of digital divide.

KEY TERMS AND DEFINITIONS

Digital Divide: The gap between those who have access to technology and those without. Also include those who have access to technology but are unable to utilise them due to lack of digital literacy.

Digital Literacy: The skills and competences of people in using technological platforms to produce and evaluate information through electronic means.

Digital Society: A society in which everything runs on digital technology where paperless and electronic means are the norm.

Digital Technology: The use of electronic tools and devices to produce and generate data.

E-Government: A form of digitised government where public services are delivered and processed via electronic or digital means.

Healthcare: The provision of medical care and services to the public.

Social Capital: The relationship between members of a society who work together to function effectively for the benefit of the society.

Gender Differences in Access to and Use of ICTs in Nigeria

INTRODUCTION

There are varying perceptions regarding gender equity in access to and use of information and communication technologies. Some argue that women have been maligned and are disadvantaged compared to their male counterparts while others are of the view that equal opportunities abound for both genders. Sanda and Kurfi (2013) submit that in their quest for empowerment and societal recognition, women have adopted and accepted ICTs as instruments for their advancement and empowerment. Although current information is fragmented, there is evidence suggesting that there are two schools of thought on gender differences in access to, and use of ICTs. The first school of thought argues that there are apparent gender differences in access to and use of ICTs (Kose, 2019; Olatokun, 2009; Nsibirano, 2009; Nsibirano, 2006; Agbonlahor, 2005; Brous, 2005; Stewart, 2004; Hafkin & Taggart, 2001). The second school of thought believes that women have come to a position of equal opportunities and platforms with their men counterparts in access to and use of ICTs (Olsson, Samuelsson & Viscovi, 2019; Bhandari, 2019). This view is also shared by Morahan-Martin (2000) who posit that females have reached parity with males in use of the internet and claims that digital divide in access to and use of ICT has disappeared. Gillwald, Milek and Stork (2010) also submit that women in some parts of the world have access to and make more use of ICTs when compared to men. This second school of thought also believed that male domination of the ICT field is not the case anymore.

When looking at the younger generation, especially the digital natives, the gender difference appears to be obliterated with both boys and girls seeming to be involved and interested in the use of various ICT tools, both at school and elsewhere (CERI, 2010). Furthermore, Tomte (2011) notes that there is

DOI: 10.4018/978-1-7998-3479-3.ch117

the emergence of social media with seemingly more female participation. In light of this, there is a need to explore how the gender issue appears in youngsters' use of and attitudes towards ICTs, and how they perform and interact as producers and consumers of digital contents. The need to bridge the digital divide between men and women in access to and use of information and communication technologies is necessary given that ICTs play essential roles in human development as enablers of meaningful and sustainable development (Gillwald et al. 2010). Furthermore, the United Nations Division for the Advancement of Women (2003) affirms that there is evidence suggesting that access to ICTs can break down the isolation of individuals, enhance their chances of economic and social inclusion as well as provide diverse avenues for women's social, political, and economic empowerment. To this end, ICTs are potential tools for job creation, social integration, women empowerment, poverty alleviation, and information dissemination. Consequently, access to and use of ICTs cannot be gender-defined but rather transcend gender, income, educational level, geographical location as well as social stratification.

Sorenson (2002) reports that widespread access to and use of ICTs do not necessarily give women equal position with men. Although studies have attempted to understand the gender gap, these studies only tell if women are included or excluded from access to and use of ICT without significant consideration of the factors responsible for this divide. Where attempts have been made to understand the causes of the gender divide, these tend to use dissimilar populations such as urban versus rural (Olatokun, 2009), educated versus uneducated, employed versus unemployed, and such likes without attempting a parallel assessment of gender difference using equal or similar criteria such as salary, employment, education level, social status etc. Given the importance of ICTs to women development, Gillwald et al. (2010) focused on ICTs in the context of Women in Development (WID), Women and Development (WAD) and Gender and Development (GAD). Other scholars also argue that studies on women and technology are sparse and often neglected (Kuschel Labra & Díaz, 2018; Orser & Riding, 2018; Dy et al., 2017; Kuschel & Lepeley, 2016). As interests deepen in studies focusing on gender inequality in access to and use of ICTs, there is an indication that the widespread adoption and application of ICTs to everyday life – both at home and the workplace is causing a shift towards an equilibrium in terms of male and female access to and use of ICTs. This study, therefore, assessed the gender difference in access and use of ICTs.

The following questions guided the study.

- i. Do males and females have equal access to ICTs in Nigeria?
- ii. What are ICTs mostly used by both males and females in Nigeria?
- iii. What are the factors that facilitate access to and use of ICTs among males and females in Nigeria?
- iv. What are the constraints to access and use of ICTs among male and female Nigerians?

Statement of Hypotheses

Based on the literature review, we hypothesise that

- i. There is no significant difference in access to ICTs between males and females in Nigeria
- ii. There is no significant difference in the use of ICTs between males and females in Nigeria
- iii. There is no significant difference between factors that facilitate access to and use of ICTs among males and females in Nigeria.
- iv. There is no significant difference between factors constraining access and use of ICTs among males and females in Nigeria.

BACKGROUND

13

Information and Communication Technologies – An Overview

Information and communication technology is a collective term for all technologies that facilitate the processing, access to, storage, manipulation, use and exchange of information between a sender and receiver of information across various media. ICT refers to associated technologies that facilitate all activities in the information life cycle. The importance of ICTs cuts across all aspects of human endeavours as almost every industry – agriculture, commerce, education, health, hospitality and tourism, manufacturing, and entertainment is driven by ICT. Consequently, Vernon (2001) viewed ICT as a collective word covering all those technologies, both hardware and software dedicated to the capture, storage, and processing, transmission, and presentation of information. Beyond this definition, the application of ICTs in driving socio-economic activities has had a significant impact on people's quality of life. This is because ICTs are applied in health delivery, engineering, business, and agriculture, military, security, law, politics and governance, all aspects of arts, science and education, among others.

Similarly, Tiarniyu (2003) conceived ICTs as electronic technologies for creating, acquiring, storing, processing, communicating and using information. This goes to show that ICTs are powerful tools for acquiring information that can aid better decision making. The use of ICTs involves the process in which computers and other related machines are used in the dissemination and retrieval of information, a technological approach which is now an integral part of human existence and has become a tool to access, receive, store, retrieve, and disseminate information. Information and communication technologies provide a platform for rapid global mobilisation and dissemination of information among people, industries, businesses and professions with the awareness of its benefits putting one at an edge over those who are unaware. This is one primary reason why there is a growing convergence of businesses, professionals, professions and industries through the leverage of ICTs for strategic advantage and global competitiveness.

The adoption and application of ICTs to work processes and human activities, in general, have been massive since the advent of the Internet. Dominick (2002) opines that the Internet brings the cost of communication to a level where many can afford it and thus making content creation and publication easy and faster. With the possibility of accessing an audience of millions of Internet users, creating a whole new class of mass communicators has been enabled by the use of ICTs. The role of ICTs in the production and use of knowledge has also become increasingly important as the basis for what is often coined as 'the new knowledge economy', which can be seen as a response to increasing global competition between countries and regions drawing on knowledge as the main asset. To ensure that society and individuals are included in this development, the idea of 'digital inclusion' has been advocated for in order to enhance the social, political and economic inclusion of all socially marginalised groups in which gender has been embedded. The use of ICTs in everyday activities has become a necessity for all as evident in education, commerce, health, agriculture, technology, religion, government, politics, entertainment, tourism, and the likes. This is due to increasing awareness of the use of ICTs for strategic advantage, a convergence of people, professionals and professions, media and formats, computing and office technologies.

In emphasising the importance of information and communication technologies to human endeavours, Nedum (2006) reports that ICTs have impacted education in the way teaching and learning are now delivered. This delivery mechanism takes the form of motion picture or film, film strip, slide projection, overhead transparency, Teletext and video text, reprography and photography, scanning and

faxing microchips, microfilms and microfiche, voice mail, voice processing, use of computers and the internet, and multimedia systems. These are all essentials of computer-based training (CBT), e-learning, and computer-mediated learning that help in interactive processing information services. Similarly, Sanda and Kurfi (2013) posit that ICTs are wielding an unimaginable influence on global activities as they have restructured politics and governance, economies, cultures, health delivery and administrative systems, and the likes across many countries and regions around the world. These ICT-driven changes are creating several development opportunities by contributing to information dissemination, providing a plethora of communication capabilities, increased access to technology and knowledge among others with individuals and groups having embraced ICTs globally as a tool for enhancing their varied interests. The importance of ICTs to human endeavours cannot be overemphasized as their application cuts across all human endeavours. Consequently, there is heightened emphasis on the use of ICTs for global development, leading to many innovations resulting from exposure and access to ICTs that provide people access to information beyond time and border.

Gender Issues in Access to and Use of ICTs

According to Asiabaka (2010), access refers to the ways and means in which individuals, communities and institutions are exposed to ICT and takes into consideration such elements as affordability, availability of the technologies, access point, and the times at which the technologies are available. The societal stand regarding gender disparity in access to and use of ICTs is that men have been the dominant users when compared to women. In light of this, Orser and Riding (2018) note that social influences may be more salient for women compared to men in forming an intention to use technology. In a study that determined the use of e-government in Turkey, Kose (2019) notes that there is a gender gap in use of e-government services as Turkish females are less likely to employ e-government tools compared to males. Tomte (2011) asserts that there has also been a point of departure for policymakers in their efforts to make plans and activities that address gender disparity in access to and use of ICTs. Women have long been aware of the power of knowledge and information sharing as a strategy for mobilising development efforts, economic empowerment and advancement.

The Beijing 1995 world conference on women recommended that women have equal access to economic resources. These include science and technology, vocational training, land, credit, information, communication and markets to further the advancement and empowerment of women and girls. This also includes the enhancement of their capacities to enjoy the benefits of equal access to these resources through international cooperation. Similarly, the conference emphasised the need to increase the participation of women to expression and decision-making in and through the media and information communication technologies as well as to promote a balanced and non-stereotyped portrayal of women (Sanda & Kurfi, 2013). If given the enabling environment, ICTs can be used to empower women through access to and use of information for informed decision making both at homes and for business. Furthermore, women can also use ICTs to harness generated information into new and localised knowledge for improving their businesses, accessing quality healthcare, and also share with others in the community, thus contributing towards their empowerment, self-determination and well-being. Unlike high prevalence in mobile phone use, Gillwald et al. (2010) report that being female and living in rural settlement reduced the probability of knowing what the Internet is, as well as using Internet-enabled ICTs when compared to female living in urban areas with increased access to ICTs. They further stated that similar education, employment and financial background create similar awareness in males and female in terms of access to and use of ICTs. However, women's failure to get equal education, employment as well as financial resources forms

the more significant part of their marginalisation in access to and use of ICTs. Umukoro and Tihamiyu (2017) also report that males have a higher disposition to the adoption and use of e-services delivered via information systems which are majorly an assemblage of ICTs.

Howell and Lundall (2000) emphasise that the effective use of ICT in a country impacts strongly on the competitiveness of the country's economy within the global market place and the ability of governments to deliver on their social goals. However, Heintz (2012) noted that gender-based constraints – including responsibilities for unpaid care and household work, social norms and gender roles, differences in women's access to and control over assets and finance, unequal investments in the capabilities of girls when compared to boys limit women's choices relative to men with regard to employment. In an attempt to explain this supposition, Sanda and Kurfi (2013) define gender as a socio-economic variable for analyzing roles, responsibilities, constraints, and needs of men and women within a given context and also refer to the social and cultural constructs that each society assigns to behaviours, characteristics and values attributed to men and women. The basis of the construct lies underneath the idea that these gender characteristics are natural or intrinsic, and therefore, unalterable. These gender attributes are shaped by ideological, historical, religious, ethnic, economic and cultural determinants which are usually translated into socio-economic and political inequalities, where men's activities and their attributes are perceived as essentially superior to women's. These assumptions are capable of heightening both digital and social exclusion at the disadvantage of women. The consequence could also include women missing out on critical positions in the society that could benefit the larger society.

In Nigeria and Sub-Saharan Africa (SSA), Okunna (2000) opines that gender relations are characterised by much imbalance to women's disadvantage by keeping women in subordinate positions to their men counterparts. Women are often considered to be 'naturally' nurturing – a characteristic linked to their reproductive capacity as child bearers and attribution that has permeated the field of science and technology globally. In the developing world, the male subculture sees women and their aspirations subordinate, resulting in a situation in which the marginalisation, trivialisation and the stereotyping of women are becoming glaring aspects of the human society. In consonance, Osabuohien and Karakara (2018) and Agbonlahor (2005) opine that there is a growing notion that women are not given the equal opportunity as men in access to and use of ICTs as males still have a good advantage over women. Some researcher (Madanda & Kabonesa, 2007; Nsibirano, 2006) also corroborate that women constitute a minority of users of the Internet and other related technology. Similarly, Manago and Pacheco (2019) note that young adult males and those who have been to high school were found to be more likely to use ICTs such as the internet. While this is true, there are also indications that much of society has changed over the years relating to female participation in leadership roles, politics, religion and the larger business environment. However, the pace of change in female inclusion in access to and use of technologies has been slow in developing and emerging economies when compared to developed countries. Although some scholars (Bhandari, 2019; Olsson et al., 2019; Morahan-Martin, 2000) posit that females have reached parity with males in use of the internet and related ICTs leading to a gradual disappearance of the gendered digital divide in access to and use of ICT, scholarly opinions are still nuanced in respect to the gender difference in access to and use of ICTs.

Constraints to Access and Use of ICTs: A Look Beyond Gender

With growing literature on women marginalisation in access to and use of ICTs, studies have pointed two opposite directions regarding the challenges to access and use of ICTs. Some studies (Olatokun, 2009; Heintz, 2010) show that government and society have not done enough to encourage women's effort

toward inclusive access to and use of ICTs. On the other hand, others (Sanda & Kurfi, 2013; Morahan-Martin, 2000) have shown that same factors such as low level of education, poor skill set, inadequate technological infrastructure, social and economic problems, rapid technological advancement, etc affect both male and female access to and use of ICTs. While men seek to fully integrate themselves into the technology industry thereby optimising access to and use of ICTs, women, on the other hand, lack the necessary skills to make use of ICTs and have many negative attitudes about them. Rather than address these challenges, they are often lackadaisical – so much depending on their male counterparts to get ICT related issues sorted for them. The African Gender Institute (2003), however, reports that certain aspects of culture constrain women's access to and use of ICTs especially for married women as some families still fear that women's access to ICTs may bring them into parity with their husband and erase the cultural distance upon which respect and other norms are built upon. Notwithstanding, there are some changes in women's use of ICTs in recent years as they have begun developing skills needed to operate this new technology effectively (Sanda & Kurfi, 2013) to support their businesses and aid their communication.

In recognition of women's critical role in the development of less industrialised societies, Scanlan (2004) posits that it is undoubtedly a fact that regardless of economic development level, population pressure, democratisation, globalisation, or region, women are at the forefront of development. Consequently, they must furnish themselves with requisite skills such as education, entrepreneurship, political participation, self-esteem, etc that men have explored to be placed ahead of their women counterparts. The Nigerian woman is characterised by low self-esteem because society has continued to regard her as unimportant and inferior to her male counterpart (Sanda & Kurfi, 2013; Okunna, 2000). Similarly, Siddiq and Scherer (2019) posit that prior research suggests that boys consider their ICT self-efficacy to be higher than that of girls. However, their meta-analysis study of whether the same pattern holds for students' actual performance on ICT literacy tasks showed that the gender differences in ICT literacy were significant, positive, and favoured girls though not very severe. Although this narrative is gradually changing with a limited number of women as CEOs and political office holders, a large percentage of women are still on the negative side of the socio-economic, ethno-cultural, and digital divide. Women must, therefore, address the issue of low self-esteem and begin to see themselves capable of doing what men can do in terms of access to and use of information and communication technologies for strategic advantage. Although progress has been witnessed in the area of techno-entrepreneurship where Nigerian women have become prominent in the technology industry, societal challenges have prevented women from taking up challenging tasks. Notwithstanding, David-West and Nwagwu (2018) report that efforts at bridging gender gap (SDG 5) and related use of ICTs has seen the deployment of innovative technologies in Nigeria's financial system that encourage women's access to and use of formal digital financial services. These services are delivered via mobile phones and other digital channels and have helped close the gender gap in use of ICTs and access to financial services.

Huyer and Hafkin (2007) point that a range of social, economic, and political factors affect and frame the gender divide, including socio-cultural barriers to technology use, education and skills levels, employment and income patterns, media and content, privacy and security, as well as location/mode of access. According to Gillwald et al. (2010), there is an insignificant gender difference in access to ICTs and their use when men and women share similar backgrounds. They further note that because of unequal access to the enablers of access to and use of ICTs, women generally have restricted access to ICTs and this increases as the technologies and services become more sophisticated and expensive, requiring higher levels of income and education to access and to operate. Respectively, women in lower income groups or rural areas may have more in common with men in similar situations with regards to access and us-

age of ICTs than with women who are more educated or from higher income groups. Also, as mobile phones become increasingly pervasive, their usage becomes limited by the high cost of communications.

Research Model and Conceptual Framework

Different research on the gender difference in access to and use of ICTs have been carried out, yet very few frameworks exist on the subject – notably the capability approach (Olatokun, 2009) and inclusivity model (Gillwald et al., 2010). The inclusivity model guides this study due to its fit for the variable of interest such as ICTs, gender inclusion and exclusion, access and use. The model in Figure 1 shows the relationship between predictors and their interaction with gender. *Inclusion* refers to those strategies or set of activities and facilities aimed at recruiting people into an information system and are further meant to facilitate access to and use of ICTs as well as it relates to gender society (Sorenson, 2002). *Exclusion* refers to measures or factors (collectively referred to as country dummy) that create or determine inequality between the ‘haves’ and ‘have-not’. These factors include culture, age, income, education and ethnicity. *Access* has to do with ownership either permanently or for the period of use (paid for) which has to do with social, economic and cultural factors. *Use* refers to the deployment or utilisation of systems or services consequent of affordability and skills required to manipulate ICTs for strategic advantage efficiently.

Figure 1. The Inclusivity Model (Gillwald et al., 2010).

Conceptual Framework

For suitability and adequate coverage variable wise, the inclusivity model was adopted, as shown in Figure 2. The framework portrays a relationship among variables determining access to and use of ICTs among males and female. Enablers of access and use include job requirement, income level, societal influence and academic pursuit. These constructs are perceived to drive access and use of ICTs irrespective of gender. Inhibitors to access and use of ICTs include income level, the complexity of technology, and rapid obsolescence of technology as well as religion/culture. These two groups of constructs determine access and use of ICTs. Income earners and those with jobs requiring ICTs are likely to afford technology as non-access, and use is considered as a personal choice and not due to societal exclusion unlike those with low income. The framework is useful in assessing what variables affect males and females' access to and use of ICTs.

Figure 2. Conceptual Framework of Determinants of Gendered Access to and Use of ICTs

Methodology

This study employed a survey design to understand differences in access to and use of ICTs between males and females randomly selected from a mixed population of working and non-working residents of Ibadan, Oyo State, Nigeria. Ibadan is home to Nigeria's premier university and is characterised by high traffic of economic, social and academic activities with high mobile penetration. Data was collected from 100 respondents made up of 50 males and females each using a questionnaire. The instrument used eleven items to measure access to ICTs and nine items for the use of ICTs using Likert scale. A Thurstone equal interval appearing scale was also used to measure enablers and inhibitors of access to ICTs. An independent sample t-test was used to measure the gender difference in access and use of ICTs as well as the enablers and constraints.

Results

The results of the analysis is presented and interpreted under the following sub-sections:

Demographic Characteristics of the Respondents

Table 1 shows that of the 100 respondents sampled for the study, 50% were males, while 50% were females as well. The age distribution followed as 16-25yrs (24%), 26-35yrs (60%) whereas 39yrs or above accounted for 16%. Furthermore, 7% of respondents had up to secondary education while the majority (93%) had more than secondary education. It was also observed that 50% were students, 41% of workers and 9% were unemployed in terms of occupation. However, 45% were on a salary scale of less than \$170 per month, 28% receives more than \$170 per month whereas 27% were without salary (partly because they are unemployed and also studying. The distribution of the respondents across religion showed that 24% were Islamists, whereas 71% were Christians.

Table 1. Respondents' Demographics

Variables	Category	Frequency	Per cent
Gender	Male	50	50.0
	Female	50	50.0
Age	16-25yrs	24	24.0
	26-35yrs	60	60.0
	36yrs & Above	16	16.0
Educational Level	O'Level or Less	7.0	7.0
	Above O'Level	93	93.0
Occupation	Student	50	50.0
	Working	41	41.0
	Unemployed	9	9.0
Salary Range (in Naira)	less than 20,000	25	25.0
	20,000 - 60,000	20	20.0
	above 60,000	28	28.0
	Missing**	27	27.0
Religion	Islamic	24	24.0
	Christianity	71	71.0
	Others	3	3.0
	Missing**	2	2.0

**Income level and religion remain sensitive variables that are often skipped by respondents in Nigeria

RQ 1: Do males and females have equal access to ICTs in Nigeria?

Table 2 shows that both males and females have equal (50%) access to mobile phones. However, males are reported to have higher (31%) consistency in accessing internet facilities than their female counterparts (27%). On the other hand, access to internet modems is slightly different between males (44%) and females (38%) respectively. It was also observed that access to smartphones, PDAs and Laptops was slightly higher among males (47%) when compared to females (42%). More so, access to ICTs provided by schools and offices (in the workplace) was higher with males (45%) against that of females (41%).

Table 2. Access to ICTs across Gender

<i>I have access to</i>	Categories	Male	Female	Total
Personal Phones	Always (%)	46	50	96
	Sometimes (%)	4	0	4
	Never (%)	0	0	0
Internet Facilities	Always (%)	31	27	58
	Sometimes (%)	19	23	42
	Never (%)	0	0	0
Internet Modem	Always (%)	22	19	41
	Sometimes (%)	22	19	41
	Never (%)	6	12	18
Smart Phones, PDAs/Laptops	Always (%)	36	32	68
	Sometimes (%)	11	10	21
	Never (%)	3	8	11
ICTs in my Office/School	Always (%)	24	19	43
	Sometimes (%)	21	22	43
	Never (%)	5	8	13

RQ 2: What ICTs are mostly used by males and females in Nigeria?

Table 3 reveals that the ICTs mostly used by males and females are mobile phones (98%) followed by Laptops and PDAs (92%), desktop computers (91%) and the internet (89%). Other ICTs are seldom patronised for use as shown with as low as (11%) of the respondents involved in the use of these technologies (other than the mobile phone, computers – *desktops and laptops*, PDAs and the Internet).

Table 3. Frequently Used ICTs by Males and Females

<i>I make use of</i>	Response	Male	Female	Total
Mobile Phone	Often (%)	49	49	98
	Rarely (%)	0	0	0
	Never (%)	1	1	2
Computers (Desktop)	Often (%)	46	45	91
	Rarely (%)	1	1	2
	Never (%)	3	4	7
Laptops and PDAs	Often (%)	47	45	92
	Rarely (%)	0	1	1
	Never (%)	3	4	7
Internet	Often (%)	47	42	89
	Rarely (%)	0	1	1
	Never (%)	3	7	10
Others**	Often (%)	8	2	10
	Rarely (%)	0	1	1
	Never (%)	42	47	89

RQ 3: What factors facilitate/necessitate the access to and use of ICTs among males and females?

Table 4 shows the factors which facilitate/necessitate access to and use of ICTs among males and females. The result shows that academic studies (78%) received the highest response as a factor which drives both males and females in accessing and using ICTs. This was distantly followed by job requirement (58%), social influence (55%) and lastly, income level (49%) respectively.

Table 4. Factors that facilitate/necessitate Access and Use of ICTs

Factors	Response	Access and Use
Job Requirement	Yes (%)	58
	No (%)	41
	Undecided (%)	1
Income Level	Yes (%)	49
	No (%)	50
	Undecided (%)	1
Social Influence	Yes (%)	55
	No (%)	43
	Undecided (%)	2
Studies	Yes (%)	78
	No (%)	21
	Undecided (%)	1

RQ 4: What are the constraints to access and use of ICTs among males and females in Nigeria?

As shown in Table 5, only income level and cost of acquisition of information and communication technologies were the significant constraints to access and the use of ICTs. All other identified factors were not key constraints to access and use of ICTs by males and females.

Table 5. Constraints to Access and Use of ICTs

Constraints	Response	Access and Use
Income Level /cost	Yes (%)	70
	No (%)	30
	Undecided (%)	0
Complexity of Technology	Yes (%)	37
	No (%)	61
	Undecided (%)	2
Rapid Obsolescence of Technology	Yes (%)	40
	No (%)	57
	Undecided (%)	3
Culture/Religion	Yes (%)	11
	No (%)	87
	Undecided (%)	2

Test of Hypotheses

The result of the analysis of independent sample t-test for difference of mean for each of the hypothesis formulated is presented below.

H₀₁: *There is no significant difference in access to ICTs between Nigerian males and females:* Although Table 6 shows that there is a difference in the means of males (2.66) and females (2.57) in respect to access to ICTs, Table 7 shows that this difference between males and females' access to ICTs is not statistically significant ($t=-0.538$, $df=98$ and $p=0.296>0.05$; 1-tailed). *The null hypothesis was, therefore, not rejected.*

Table 6. Group Statistics

	Gender	N	Mean	Std. Deviation	Std. Error Mean
Access to ICT	Male	50	2.57	.375	.053
	Female	50	2.66	1.064	.150

Table 7. Independent Samples Test

Access to ICT	Levene's Test for Equality of Variances		t-test for Equality of Means				
	F		T	Df	Sig. (2-tailed)	Mean Diff	Std. Error Diff
Equal variances assumed	1.445	0.232	-.538	98	.592	-.086	.159
Equal variances not assumed			-.538	60.976	.593	-.086	.159

H₀₂: *There is no significant difference in the use of ICTs between Nigerian males and females:* The result presented in Table 8 shows there is a difference in the use of ICTs between males and females (2.62 and 3.84 respectively) with females using ICTs more than males. At Levene's $p<0.05$ (equal variances not assumed), Table 9 shows that the difference between males and females is not statistically significant ($t=-1.258$, $df= 49.141$ and $p=0.107>0.05$; 1-tailed). *The null hypothesis was, therefore, not rejected.*

Table 8. Group Statistics

	Gender	N	Mean	Std. Deviation	Std. Error Mean
ICT USE	Male	50	2.62	.260	.037
	Female	50	3.84	6.850	.969

Table 9. Independent Samples Test

Use of ICT	Levene's Test for Equality of Variances		t-test for Equality of Means				
	F	Sig.	t	Df	Sig. (2-tailed)	Mean Diff	Std. Error Diff
Equal variances assumed	5.558	0.020	-1.258	98	0.211	-1.220	0.969
Equal variances not assumed			-1.258	49.141	.214*	-1.220	0.969

H₃: *There is no significant difference in factors that enable access to and use of ICTs between males and females Nigeria:* Table 10 shows there is a difference between the means (2.67 and 4.44) of males and females with respect to enablers of access to and use of ICTs. At Levene's $p > 0.05$ (equal variances assumed), Table 11 further shows that difference between males and females in terms of enablers of access to and use of ICT is statistically significant ($t = -2.502$, $df = 81.534$ and $p = 0.007 < 0.05$; 1-tailed). *The null hypothesis was, therefore, rejected.*

Table 10. Group Statistics

	Gender	N	Mean	Std. Deviation	Std. Error Mean
Enablers of access to and use of ICTs	Male	50	2.67	2.628	0.372
	Female	50	4.44	4.264	0.603

Table 11. Independent Samples Test

Enablers of access to and use of ICTs	Levene's Test for Equality of Variances		t-test for Equality of Means				
	F	Sig.	t	Df	Sig. (2-tailed)	Mean Diff	Std. Error Diff
Equal variances assumed	10.638	0.002	-2.502	98	0.014	-1.773	0.708
Equal variances not assumed			-2.502	81.534	0.014	-1.773	0.708

H₄: *There is no significant difference the inhibitors of access to and use of ICTs between males and females in Nigeria:* Table 12 shows that there is a difference between the means (2.30 and 2.59) of Nigerian males and females. With equal variances assumed (Levene's $p > 0.05$), it is also observed from Table 13 that the difference in inhibitors to access to, and use of ICTs between males and females is not statistically significant ($t = -0.276$, $df = 97.796$ and $p = 0.392 > 0.05$; 1-tailed). *The null hypothesis was, therefore, not rejected.*

Table 12. Group Statistics

	Gender	N	Mean	Std. Deviation	Std. Error Mean
Inhibitors of access to and use of ICTs	Male	50	2.30	5.126	0.725
	Female	50	2.59	5.365	0.759

Table 13. Independent Samples Test

Inhibitors of access to and use of ICTs	Levene's Test for Equality of Variances		t-test for Equality of Means				
	F	Sig.	t	Df	Sig. (2-tailed)	Mean Diff	Std. Error Diff
Equal variances assumed	0.191	0.663	-0.276	98	0.783	-0.290	1.049
Equal variances not assumed			-0.276	97.796	0.783	-0.290	1.049

Solutions and Recommendations

This study found that males and females have equal access to and information and communication technologies, although males were found to be more consistent in accessing internet facilities than their female counterparts. This found support in Morahan-Martin (2010) that there is a gradual shift towards equality in males and females' access to and use of ICTs. Sanda and Kurfi (2013) also posit that in recent years, there have been changes in women's access to and use of ICTs as women are now developing skills and capabilities needed to utilise existing and emerging technologies effectively. Today's emergent digital economy also means that daily routines are now facilitated by basic ICTs and would require the acquisition of IT capabilities in order to effectively use them (Umukoro & Tihamiyu, 2017; Sanda & Kurfi, 2013; Gillwald et al., 2010; Nedum, 2006). As noted by the United Nations Division for the Advancement of Women (2003), access to and use of ICTs can foster socio-economic inclusion of individuals, enhance their chances of a better quality of life as well as provide diverse avenues for women's social, political and economic empowerment.

The study also found that mobile phones, computers (desktops and laptops) personal device assistants (PDAs), and the internet have become mainstream ICTs used by both males and females in Nigeria. This has become a way of life given that these technologies facilitate processes and activities in education, health, business (commerce), banking, tourism and entertainment, and the likes. Howell and Lundall (2000) emphasise that the effective use of ICTs in a country can impact strongly on the competitiveness of that economy within the global marketplace and government's ability to deliver on its social goals. This is because ICTs can help all social strata to be more productive, especially those at the bottom of the pyramid (BoP). More so, the study shows that the internet and other related ICTs aid social inclusion, especially among women whom socio-cultural norms might have worked against in developing countries. Through ownership of smartphones and remote access to the Internet, women now have improved access to information for improved decision making that enhances their quality of lives.

On the enablers of access to and use of ICTs, the study showed that educational demand (studies), job requirement, need for social inclusion and societal influence, as well as income level, are significant factors that drive access to and use of ICTs among males and females. This is strongly supported by the findings of Nedum (2006) that ICTs have become an integral part of education, communication, health and other aspects of human endeavour. As such, the need to be connected on the go, work seamlessly and remotely can drive the adoption and use of ICTs among men and women. Umukoro and Tihamiyu (2017) also corroborated this fact that the deployment of ICTs in education is a critical enabler of access to and use of ICTs. On the other hand, the study showed that among the factors identified as inhibitors to access and use of ICTs, only income level received a unanimous agreed response. Technology

sophistication, rapid obsolescence of technology as well as culture and religion were not considered as major constraints to ICT access and use. These findings are contrary to those of Sanda and Kurfi (2013), Huyer and Hafkin (2007), and Morahan-Martin (2000) who argued that rapid obsolescence of technology, as well as culture and religion, affect gender access to and use of ICTs. It is true that income level determines the standard of living and can be inferred that those with the financial capability, irrespective of gender will always access and use ICTs for strategic advantage.

The study also showed that there is no significant difference in access to ICTs between males and females. This is explained by the fact that males and females are becoming increasingly aware of the benefits of information and communication technologies' application to human activities for personal and national development. There are mixed opinions on the concept of gendered access to and use of ICTs with some researchers positing that gender differences still prevail while others are of the school of thought that a significant level of equality is being attained as a result of a growing awareness among both males and females on the numerous benefits of ICTs. The current study found that there is no significant difference in the use of ICTs among Nigerian males and females. In consonance, Sanda and Kurfi (2013) submit that women in their quest for empowerment and societal recognition have adopted ICTs as instruments for their advancement and empowerment. Also, Partey et al. (2018) report that both men and women have been cited as very responsive to technology adoption under different contexts. The 'closing gap' in access to and use of ICTs reported by Morahan-Martin gave credence to this finding. As stated by Dominick (2002), ICTs' adoption and application to everyday human activities is a sure way to reducing the cost of communication to a level where many can afford them thus creating an environment of inclusivity in the social, political, entertainment, tourism, health, education and other human environments which man must constantly relate with.

This study also found a significant difference between factors that facilitate males' access to/use of ICTs and those of females. This contrasts Morahan-Martin (2000) and Sanda and Kurfi (2013) that same factors such as low level of education, poor skill set, inadequate technological infrastructure, social and economic problems, rapid technological advancement, etc affect both male and female access to and use of ICTs. This may be because while men seek to fully develop and integrate themselves with the technological innovations thereby optimising access to and use of ICTs, women, on the other hand, are not at par with their male counterparts in terms of the necessary skills to utilise ICTs effectively. In as much as equal opportunities abound for both males and females, this difference in factors motivating males toward access to and use of ICTs can be accounted for by female' low self-esteem in ICT use (Sanda & Kurfi 2013; Okunna, 2000) and the impact of culture in the girl child education. Unlike the observed difference in the enablers of access to and use of ICTs among males and females, the current study found no gender difference in constraints to access and use of ICTs. People within same settlement patterns (i.e. rural-rural, urban-urban), employment/job status and requirement, religion/culture, educational level as well as same social strata are affected by same factors such as low level of education, poor skill set, inadequate technological infrastructure, social and economic problems, rapid technological advancement, etc. in their access to and use of ICTs (Sanda & Kurfi, 2013; Morahan-Martin, 2000). Economically buoyant individuals have a higher tendency to cope with technology change, job requirements that necessitate the acquisition or upgrade of their skill set to cope with evolving ICTs and so much more, whether males or females. On the other hand, people with low-income earnings, low level of education as well as poor skill sets are always faced with same constraints such as inability to afford needed ICTs, lack of skills to operate these technologies even when provided, etc.

Future Research Directions

There are numerous studies on equal rights and full participation of women in all spheres of life. However, the gender divide is still dominant among disadvantaged groups, especially those with low-income and low level of education. Given that women constitute the majority of national populations, most of whom live in rural and peri-urban areas, there is a need to assess how the gender difference plays out among disadvantaged groups. Findings from studies of this nature will help in developing appropriate interventions for women in these groups, especially in the area of ICT use in agriculture, health, education, and others; as well as interventions in science, technology, engineering, and mathematics (STEM).

CONCLUSION

This study has shown that there is a disappearing difference in access to and use of ICTs between males and females. Although females are embracing the use of ICTs at a rapid rate, uptake among males still tends to be higher, albeit not statistically significant. Brussevich et al. (2018) note that on average, women perform more routine tasks than men across all sectors and occupations and that such tasks are most prone to automation. As such, fostering gender equality and empowerment in the changing landscape of work remains an imperative such as endowing women with the requisite skills through investment in women in STEM fields. Also, there is a need to bridge the digital divide through access to and use of new technologies to close gender gaps to improve women's labour market prospects in the new world of work. The enablers of access to and use of ICTs tend to be different among males and females. To deepen ICTs adoption and use among females, government's ICT policies and programmes must address the needs of women. While prior literature on gender difference in access to and use of ICTs agree that there is a disequilibrium despite the growing awareness of the benefits derivable from these technologies, this study has shown otherwise. An assessment of the level of inequality in gender's access and use of ICTs is germane to ascertain the extent of its impact (if any) and the causes of a gender-driven digital divide in order to identify measures of attaining equilibrium between males and females. This study has provided insight into the measures that need to be taken in addressing issues of gender inequality in access to and use of ICTs. It is, therefore, recommended that further research effort should be made using a larger sample. Also, a study of this nature that focuses on gender access to and use of ICTs in the public sector will help in the modernising of government through the effective deployment for serving better public sector service delivery.

KEY TERMS AND DEFINITIONS

Access to ICTs: This is an individual's unrestricted ability, right, or permission to locate and use of an information and communication technology device such as computers, mobile phones, the internet and the likes for the receipt, processing, storage, retrieval, consumption, and dissemination of information.

Digital Divide: This is the gap between technological "have" and "have not" individuals, geographic locations or demographic groups.

Gender: This is a social construction that refers to the roles developed by male and female in response to their environment, especially concerning socio-cultural differences rather than biological ones.

Gender Difference: This is the difference in males and females' mental functions and behaviours that affect their access to and use of information communication technologies as a result of a complex interplay of biological, developmental, and cultural factors.

Information: This is defined as processed data and facts to which meanings have been assigned for the purpose informed decision making that results in a change in behaviour or action as a result of its use or consumption.

Information and Communication Technology: This is a term used for describing all technologies that facilitate the processing, access to, storage, manipulation, use and exchange of information between a sender and receiver of information across various media.

Information and Communications Technology for Development (ICT4D): This refers to the use of technology for helping poor and marginalised individuals and communities in developing countries to bridge the digital divide and aiding economic development by ensuring equitable access to up-to-date communications technologies.

Use of ICTs: This is the utilisation of information and communication technologies for accessing and consuming information and information services consequent of affordability and skills required to manipulate ICTs for strategic advantage efficiently.

How Mobile Technologies Are Leading to Economic Development in Sub-Saharan Africa

Nigel McKelvey

Letterkenny Institute of Technology, Ireland

Kevin Curran

Ulster University, UK

INTRODUCTION

Mobile technology today is increasingly being used to help improve under developed and developing areas such as sub-Saharan Africa. With the statistics showing the number of adults in Africa owning mobile devices steadily increasing, mobile technology has been a popular area of interest to use to help improve areas such as healthcare and education throughout African cities and rural areas. Common that ways mobile technology is being used to help the residents of sub-Saharan Africa are in the sectors of health care and education. Mobile technologies being used in these areas whilst simple are incredibly effective and successful in helping to better the quality of health in education in sub-Saharan Africa. Many of the projects and systems developed using mobile technology focus mainly on urban areas. While reports state the huge increase in the number of those using mobile devices in Africa, along with the large estimated increase in the coming years, the difference between rural African countries and countries which contain urban cities is substantial.

Other uses of mobile technology in African cities includes topping up smart cards with mobile devices for the distribution of clean water as well as the delivery of vouchers which can be exchanged for healthcare equipment. This chapter will show how mobile devices are being used to track and monitor the outbreak of malaria in sub-Saharan Africa and is applied to a system to help ensure health care facilities in areas with affected residents have the capacity to deal with those who have contracted the disease. We also outline the ethical effects of using the mobile devices and how they are affecting the residents of sub-Saharan Africa.

BACKGROUND

Mobile Technology is a sweeping term covering many different areas of technology. Many of the uses for this technology in developed countries include helping with general day to day operations for the user such as online banking, shopping, or social media applications. Mobile technology is a sector which is growing rapidly, and also merging with other sectors to help make use of the technologies full potential. One of the areas where mobile technology has been proven to be successful, is when using

DOI: 10.4018/978-1-7998-3479-3.ch118

simple technology and mobile devices to help developing countries such as Africa (Aker & Mbiti, 2010). Many different organizations and companies are using mobile technology to accomplish huge feats for rural African villages (Abuka, 2016). A leading success story has been the M-Pesa service launched in 2007 by Vodafone for Safaricom and Vodacom. This has generated mobile money revenues of more than \$300 million in 2004. This makes it the most successful mobile transfer service at this time. It has now expanded to Afghanistan, South Africa, India and Eastern Europe. It seems to have found its niche market. In Kenya alone, mobile money transactions totalled \$22+ billion in 2013. Other African countries such as Sudan, Somalia, Tanzania, and South Africa are also huge revenue generators for operators as well (BBC Africa, 2015).

In today's world when discussing developing countries, the most commonly mentioned country is Africa. Africa is known worldwide for its widespread poverty, levels of education, unsanitary living conditions, gang violence and high mortality, and birth rates. Many companies and organizations are now turning to mobile technology to help combat these issues facing those living in Africa. With the increase in advancements in technology, many organizations and companies are researching and looking into how some technologies could be adapted to help reach areas which are usually not easily accessible. A simple yet effective method at developing communication with these areas is through mobile devices. In recent years the ownership of mobile phones in Africa have increased rapidly, with the percentage of adults who own a phone rising from 64% in 2002 to now match the US with 89% in 2014 (Global, 2015). An infographic depicting this information can be seen in the appendices chapter as image 1.0. As shown in reports conducted by Pew Global (2015), the most popular activity for mobile phone users in Africa is sending text messages. The report shows that 80% adult cell phone owners use their phone mostly to send text messages as seen in infographic image 2.0 in the appendices chapter below. SMS is arguably the most popular activity in this area due to the fact that many in this area only have ownership of a cell phone rather than smartphone, with a study conducted on Nigerian residents showing that although 89% of the population there owned a mobile phone only 27% owned a smartphone (Pew Global, 2015).

MOBILE TECHNOLOGY IN AFRICA

Africa is known for its lack of proper infrastructure, and industrialization. Technology is not something that is commonly associated with Africa. The main contributing factor for this being that mostly all technology needs to be powered in some way. A study by The World Bank (2013), showing that 76% of sub-Saharan Africa is without access to electricity, the possibility of being able to use technology within these areas decreases drastically. Another area of technology which is obstructing the growth of use of technology in Africa is connectivity. A study by iPass, (2014) shows that if growth in connectivity hotspot numbers continue to grow at the same rate as previous years then by 2018 there will be a WiFi beacon for every 20 people on earth, however only one beacon for every 400 Africans.

Education

The use of mobile technology has been hugely influential in the improvement of education throughout Africa (Asongu et al., 2016). The need for helping improve education throughout sub-Saharan Africa has been a main priority for many organizations, one of which was Oxfam. Oxfam are a charity organization which help in delivering medical aid, supplies and help to a number of different countries including Africa (Oxfam, 2016). One particular project which Oxfam began was to help improve sub-Saharan

resident's knowledge on different diseases which were quite common in the areas however easily preventable. Oxfam developed an SMS delivery system, which would send out four texts daily with educational information on the different diseases and how to prevent against them. This was incredibly simple as the only technology needed for the residents was a simple mobile phone which could send and receive SMS.

Health

Mobile technology is also being used to help better the health services in areas of sub-Saharan Africa (Asongu et al., 2018a). Organizations and companies such as UNICEF are using simple mobile technology to help teach about how to prevent from contracting diseases, help improve distribution of medical supplies and equipment to people who would otherwise not have access to the materials. They are also helping to monitor and ensure medical facilities contain the stock levels needed to combat against diseases. Two of the main diseases technology had been used to battle the spread of was polio and malaria.

Polio

Alongside the project discussed earlier to help better educate areas of Africa about the polio and how it can be contracted, a project was also launched that would help provide the equipment and sanitary supplies needed to help prevent the spread of the disease to rural and hard to reach areas. The project would also work through SMS where the users would receive a SMS with a mVoucher. As stated by Textello (2016), the mVoucher or mobile voucher is a unique code, each code is created using the customers contact number, resulting in each customer and code being linked, this then reduces the problem of multiple claims, and users mVouchers being stolen. The user would then present their code to a registered trader, where they would then in return receive the specified package containing the items and supplies needed (Oxfam, 2015).

Malaria

To help combat against the threat of malaria in different areas of Africa another project also using SMS was created (Asongu et al., 2018b). This project was however to help survey the outbreak of the disease, and help get real time accurate updates on the impact of the disease. A system to combat malaria such as this was needed as malaria is still a large threat, particularly to children as indicated by the World Health Organization (2015), detailing that a child dies every two minutes in sub-Saharan due to malaria. Rather than simply just supplying information on the disease and vouchers for equipment to prevent from contracting the disease like done with the polio SMS system, the new system would “improve access to essential malaria medicine in areas of developing countries” (Novartis, 2014). The new SMS system created was called “SMS for life”. SMS for life uses common technology to help achieve its goals of eliminating medical facilities from depleting stock levels completely, increase access to essential medicines needed for those infected with the disease and to help reduce the amount of deaths caused by malaria.

SMS for life is a web based system which makes use of a SMS management tool, this then links with a web based application created for reporting (Yeboah-Asiamah et al., 2018). The system uses the SMS management tool to store the number of a health worker from each of the medical facilities registered in the area, SMS for life then uses a short code number that allows the health facility employee to receive an SMS with a data request, and send an additional SMS with the requested data counts completely free. The data sent from the health worker is then manipulated by the online reporting system, which

makes it available for viewing online by a higher body, usually the District Health Management Team. The higher body view this information on the SMS for life website by password, this allows a secure method of monitoring the malaria surveillance in each medical facility in the area (Githinji, et al., 2014).

Water ATM's

In some areas in Africa, local governments have teamed with Grundfos, a Danish water engineering company to install “water ATM’s”. The water ATM’s work by have having a water dispenser installed with users having an account with the dispenser. Each user then receives a smart card, these smart cards and accounts are topped up through mobile phones. The water dispensers can then be activated by the smart card. The user simply scans or swipes the smart card to be dispensed clean, safe water (Wesangula, 2016).

This project has brought water to many different areas of rural Africa and has now began to be installed in more urban areas such as Nairobi (BBCAfrica, 2015). As stated by Mourdoukoutas (2015), there are still some issues with the systems however Rasoul Mikkelsen, Grundfos director for global partnerships believes that “he project will have a huge positive impact on health. It is an affordable system with sustainable, good quality water,”.

As well as the projects discussed above there have also been systems developed using SMS to help monitor Zambia for measles outbreaks, allow HIV sufferers health workers to send information on patient status as well as inform their patients details of their anti-retroviral therapy (Aker & Mbiti, 2010).

SOLUTIONS AND RECOMMENDATIONS

It is clear to see that the results of the Polio projects mentioned above have been extremely successful. An evaluation report by Oxfam (2015) stated that the project had a reach of 104,358 residents receiving the text which in turn was estimated with a reach of 1 million people, this was a completion rate of 86%. These people are now much more educated on how to better protect themselves against Polio, giving not just those who received the informative SMS messages but also those who were in communication with them, a better standard of living and a greater opportunity at life. Also with the pairing of the mVouchers for sanitary supplies and equipment to prevent contraction, with the educational messages it gives an incentive, as it gave the participants of the scheme something physical alongside the messages, something that they can then use the information received to put into practice (Oxfam, 2015).

However, there were some issues surrounding the project. The mVoucher system feedback report shows that the amount of participants that received the voucher compared to the amount of vouchers collected varies greatly with 71.4% of those who received a voucher declining to redeem it (Oxfam, 2015). Oxfam distributed a household survey to each of those who participated in the project, the survey asked the participants if they had collected their supplies with the voucher and if not then why? The main reason given for not claiming the supplies was “Distance to distribution Centre”, this highlights how these projects seem to be specifically targeted at more urban areas rather than the outer lying rural areas of sub-Saharan Africa which is usually in greater need of the aid. This can also be seen in the number of distributors in each district, when the project began it was outlined that each district was to have 3 traders and 15 distributors, however this did not happen in every district, because of the lack in distributors the resulting distribution was below expected capacity, with fewer distribution points (Oxfam, 2015).

Issues can also be seen with the water ATM's which have been implemented in certain cities throughout Africa. Although the ATM's have achieved their goal of delivering safe clean water to different parts of the city, they too can be seen to be focused on the urban areas. As discussed in an article by Mourdoukoutas (2015), it states that Mr. Gichuki, the managing director of the Nairobi Water and Sewerage Company, said that "the Nairobi Water and Sewerage Company has so far identified 611 more points to install the dispensers and aims to eventually install one every 100 meters throughout the city". Meaning the residents from more rural secluded areas are left having to travel further for clean water when those who live in the cities have multiple choices for where to receive their water from, as well as having to wait longer before the installation of a water ATM in a nearer location. This again shows the imbalance between the urban and rural parts of sub-Saharan Africa.

FUTURE RESEARCH DIRECTIONS

The effects of the increased use of mobile technology can be seen in many areas, and with numbers showing that Africa has had the fastest growing region in the years 2009 to 2014, and as stated in a report by GSMA intelligence (2014), is predicted to continue to grow at a rate of 7% annually until 2020. These figures show the level of growth expected for Africa however when looking at figures relating to each individual country a drastic imbalance can be seen. As shown in the report by GSMA intelligence (2014), the breakdown of the number of subscribers to mobile phone providers show the harsh difference between the more urban countries and the more rural countries. For example, the percentage of subscribers in Mali is 70%, compared to the considerably smaller percentage of 22% in Ethiopia. This large margin shows the growing issue of the difference between these two areas, an issue which needs to be examined. As stated in a report by Aker & Mbiti (2010), more examination of the possible impacts that could occur is needed, the report suggested that "careful evaluations of mobile phone development projects are required for better understanding of the economic and social outcomes".

CONCLUSION

From researching and examining how mobile technology has helped improve sub-Saharan Africa, in the different areas of health and education, it is clear that the technology and the projects it was used in has greatly benefited the African residents. The educational system created to aid those at risk of polio helped residents learn cleaning procedures and how to use the sanitary items provided with the mVouchers also distributed through mobile devices also (Okello et al., 2018). The use of mobile devices has also helped service those suffering from malaria, as it ensures that those needing treatment's local health facility will always be within capacity, thanks to the "SMS for Life" system. Finally, the statistics outlining the difference from the rural and urban areas of sub-Saharan Africa, show how the effect differs from region to region. To conclude the chapter, it is evident from the information presented that mobile technology has greatly helped improve different areas of life such as education and health (Porter et al., 2016). However conversely the effects of the increased use of mobile devices in Africa has contributed to a poverty imbalance and perpetuating health inequalities between the urban and rural areas of sub-Saharan Africa, and its possible impacts is an area that needs to be greatly researched before any implementation of larger projects can begin.

KEY TERMS AND DEFINITIONS

Advance Fee Scam (Nigeria 419): Is an advance fee fraud which involves a payment in advance with the promise of wealth, wills, gifts, employment or prizes. The scammer contacts their intended target via mail, phone, fax, or email. Originally known as the Spanish Prisoner Letter it has been carried out since at least the 16th century via ordinary postal mail. Section 419 of the Nigerian Penal Code prohibits this type of activity and it has often referred to as ‘419 frauds’ or ‘Nigeria 419’.

Developing Countries: Are often referred to as underdeveloped countries and they refer to countries where there is a less developed industrial base and they have a low Human Development Index (HDI). Developing countries differentiate from developed countries in that the people have a lower life expectancy, lower standard of education and the people of developing countries have a lower income and thus less money.

Ethical Standards: Are principles which when followed will promote values such as trust, good behaviour, fairness, and/or kindness. One consistent set of standards that all companies follow does not exist but rather each company has the right to develop a set of standards which are meaningful to that particular organization.

Information and Communication Technology (ICT): Is an umbrella term which includes any communication device or application, encompassing: radio, television, cellular phones, computer and network hardware and software, satellite systems and so on, as well as the various services and applications. The term ICT however has no set definition as the concepts methods and applications involved in ICT are constantly changing almost on a daily basis.

Mobile Point of Care (MPOC): Involves the use of multitasking devices which support clinician use cases, improve productivity, streamline communication and bridge the gap between inpatient and outpatient care. This fast growing area provides an abundance of apps for mobile devices and will change the way healthcare is delivered providing the opportunity for remote monitoring, measuring drug response, tools for drug development and diagnostic assistance for point-of-care and management of chronic or infectious disease.

Mobile Technology: Is a technology which is used for the purpose of cellular communication. The standard mobile device has moved from being a simple two-way pager to being a mobile phone. Mobile technology as the name implies refers to a technology which is portable. Examples of mobile IT devices include laptops, netbook computers, tablets, smart phones, global positioning system (GPS) devices.

Monitoring Applications: Involve the use of a technology to enable the monitoring of patients while outside of conventional clinical settings (e.g., in the home), which may increase the access to care and decrease the cost of delivering healthcare.

Personal Data: Refers to data relating to a living individual who is or can be identified from the data or using the data in conjunction with other information which is in or likely to come into the possession of the data controller.

Short Message Service (SMS): Is a simple text messaging service component found in phones, the Web, or in mobile communication systems. It adopts a series of standardized communications protocols which enables either fixed line or mobile phone devices to exchange short text messages. More commonly referred to using the term “SMS” it is used for both user activity and all types of short text messaging in many parts of the world.

Sub-Saharan Africa: Geographically refers to all the areas of the continent of Africa which lie south of the Sahara Desert. Some of the countries which fall into this category include countries such as Kenya, Ethiopia, Ghana, Nigeria, and South Africa.

INTRODUCTION

The information at the end of the twentieth century became an important factor of production, although it was always present in the history of mankind, but it did not always have the same importance as it has in the post-capitalist society. In the Middle Ages people lived from what the earth produced, cultivated it and lived according to the productive cycles of the seasons.

The craftsman lived and had the workshop in the same place. It produced the works according to customers' requests, producing the final products (their art). With the Industrial Revolution, the worker began to live in function of the clock and the completion of tasks, one after another, until the whistle of the factory announced the end of the work day. The worker did not need to know what would be done with the result of his work, that is, what was the final product. The worker lost the relationship between the work performed (production) and its result.

Marx separated the worker from the product of his work, at the factory, having invented the work as something separate from the worker. The notion of product and production began to belong to the owners of the factories. In the factory it became necessary to control the production on a large scale, and for this, the production administration was invented. The scientific administration developed the conditions of productivity in an unprecedented way and prepared the mechanization of the tasks before performed by parts of the human body. At the limit, manufacturing production could be fully mechanized and dispense with all workers, minus supervisors. Someone would have to control the machines.

Focus and Approach Methodology

As for its nature, the research is qualitative, since it does not claim to quantify events or privileges the statistical study. Its focus is to obtain descriptive data, that is, the incidence of topics of interest in two fields, the information Sciences and the Sciences and Management. Consequently, about the extremities, the research is exploratory in nature and descriptive, as the technique used, is categorised, consensually, as a study of direct documentation, which provides for the consultation of sources Related to the study in different media, printed or electronic.

BACKGROUND: FUNDAMENTAL CONCEPTS

Information and Knowledge

Although the terms information and knowledge are used very often, they are not the same thing. Information is not the same as data, although the two words are often confused, so it is understood that the

DOI: 10.4018/978-1-7998-3479-3.ch119

subtle distinction between these concepts is essential. Data do not convey meaning or meaning of facts, images or sounds, since they lack relational elements indispensable to the establishment of a complete meaning, lacking an internal relational structure for a cognitive purpose.

This structure is one of the attributes of information. Data becomes information when its creator adds meaning (Davenport and Prusak, 1998). William G. Zikmund (2000, p.19) defines knowledge as “the mixture of information, experience and understanding that provides a framework that can be applied to the assessment of new information or new situations”. Information “feeds” knowledge. Knowledge can thus be defined as a person’s ability to relate complex information structures to a new context.

New contexts imply change, action and dynamism. Knowledge cannot be shared, although the technique and components of information can be shared. When a person internalizes information to the point of being able to use it, we call it knowledge (Zikmund, 2000). This is a fluid mix of structured experiences, values, contextual information and expert insight that provide a framework for evaluating and incorporating new experiences and information. In organizations it is found not only in documents and reports, but also in organizational routines, processes, practices and standards.

Knowledge has its origin and is applied to the minds of connoisseurs (Davenport and Prusak, 1998, William Zikmund, 2000). Knowledge is information as valid and accepted, integrating data, acts, information and sometimes hypotheses. Knowing requires someone to filter, combine and interpret information. Information can be considered as a “substance” that can be acquired, stored and owned by a person or a group and transmitted from person to person or from group to group.

Information has a certain stability and may be better viewed as existing at the societal level (Davenport and Prusak 1998). Although we may store it by employing various physical supports, the information itself is not physical, but abstract and so purely mental. Knowledge is stored in people’s memory, but information is out there in the world. Whatever it is, there is somewhere between the physical world around people and the mental world of human thought.

Knowledge = Internalized information + Ability to Use It In New Situations

Knowledge lies fundamentally and intrinsically within people. These are more complex and unpredictable at the individual level than an entire society, so it is not surprising that knowledge is much harder to obtain than information. Knowledge exists mainly within people; it is an integral part of human complexity and unpredictability.

Knowledge has a fundamental duality: it is something storable (at least sometimes we intend to do so) and something that flows (something that communicates from person to person). It is possibly the duality of knowledge (thing that flows and the storage process) that makes its treatment and management difficult. According to Dahlberg (2006) knowledge is organized into knowledge units (concepts) according to their characteristics (objects / subjects / subjects). Knowledge organization is related to a process of conceptual analysis of a knowledge domain and from there it is structured / archived generating a representation of knowledge about such domain that will be used for the organization of information about that knowledge domain.

Resource

A resource is anything that can be thought of as strength or weakness for an organization, so that it gets a competitive advantage if it acquires or develops superior resources or a combination of superior resources.

Teece, Pisano and Shuen (1997) define how the specific assets of a company's resources are difficult, if not impossible to imitate. In turn, Prahalad and Hamel (1990) define the resource as "nuclear Powers".

A feature incorporates several strategic management skills to explain how some organizations have superior performance to their competitors. This view means that organizations are a set of resources and capabilities in which the first management task is to maximize the value of existing resources and capabilities, while developing the basis of the resources of the Future, (Grant 1991, p. 110).

The distinction between resources and services consists of the following: the resources are a set of services and the potential that can be defined independently of their use, while the services cannot be defined (Penrose, 1959, p. 25). The capacities of an organization at a given time are those of tangible or intangible assets that are connected to the organization as capital, equipment, skills and knowledge of workers, brands and technological Systems (Wernerfelt 1984, p. 172).

However, few resources are productive, but require cooperation and coordination together. This capability of the resource pool to perform some tasks or activities, is referred to as a capacity. In order to make productive use of this set of resources, organizations acquire resources that are called market factors, such as the labor market or capital.

Market strategic factors are defined as the markets in which organizations acquire the resources needed to market their strategic products. Organizations acquire resources as market factors, work and develop resources that make use of these resources in order to supplement the products and services that are sold in one or more markets.

Costs

Cost is an expense relative to a good or service used in the production of other goods or services. Cost calculations have been limited to those associated with product production. Some studies have been directed to the costs of the use of information and others still for the costs of certain channels of information acquisition.

Effectiveness

The evaluation of the efficacy of a service or product presupposes the comparison of objectives with the results. Efficacy is a measure that measures when we achieve a goal or to what extent we have achieved a satisfactory level of performance. The measure of efficacy is related to the maximization of results at satisfactory costs, not necessarily the minimum. The effectiveness of Information Services is seen as a desirable state when the highest level of performance is obtained, consistent with the levels of spending and resources consumed. In the analysis of effectiveness there must be a close relationship between the objectives of the services and the needs of customers (users). A measure of value and cost of each product or service is required for proper evaluation of efficacy. Thus, this analysis is valid to the extent that these items are adequately quantified. The benefits and costs that cannot be directly data, in monetary terms, can be quantified by coefficients with relative weights.

Efficiency

While the study of efficacy compares objectives and outcomes, the study of efficiency focuses on how well the activities are performed. This study has been very common in the evaluation of information services. Efficiency is related to maximising the effectiveness of spending. This implies eliminating

unnecessary expenses for the execution of defined tasks, thus seeking the minimum cost; This will not necessarily maximize performance.

Value

The VALor is an attribute that can be applied to almost anything. The notion of value is sometimes confounded with price and cost. **Price** is the monetary amount to acquire a good or service by its owner; the price defines the monetary amount that can be exchanged for the good or the service. Cost is the monetary amount spent in the production or execution of the good or service. The **value** has three characteristics: it is subjective; varies with time and can be positive or negative. The positive satisfactions of value are called “benefits” and the negative are “loss” or “damage”.

Skills

Information and knowledge became integral factors of production. Other values come into play: to innovate and deal with irregularities, it takes autonomy and responsibility, in addition to a knowledge of processes and products. Information and knowledge have always been part of the productive work, but there is now visibility, and its importance is acknowledged. As knowledge can only be mobilized by the workers, by the human person, the logic is reversed. The work is no longer the factor something external to the worker and is once again something intrinsic to those who accomplish it.

The transformations that occurred in the world of work replayed the human being at the center of production. It then goes on to talk about skills, and no more qualification for a job or a particular job. It is the person, with its most complete characteristics that matters. For a peasant or a craftsman, working meant employing and developing his knowledge, relying on rules transmitted by more experienced peers (Masters) and acquired by the individual through a series of proofs (...) was the direct expression and Immediate practical intelligence. It was the invention of work as a separate object of the worker who served to qualify another type of social relationship, that of the objective work and the capacities necessary for the *accar*. Hence the separation between the objectivity of work and the subjectivity of the worker. To get out of this logic of objectification, it was necessary that the work was again subjectivated. This meant the inclination to the logic of competence, which was called “model of competence”.

Osty (2000, p. 9) considers that the notion of competence shows the emergence of a new mode of management and recognition of the knowledge required by work situations, revealing the breadth of work transformations in the last twenty years of TWENTIETH century.

According to Zarifian (2003, p. 37), competence is a new form of qualification, a new way of qualifying. But it is not about qualification as “a particular and always dominant historical way: that of qualification by the workplace”, but rather in a new way: “The construction of qualification”. This construction of qualification, in the face of new production conditions, would replace the two previous models: the model of the profession and the model of the job (or employment). The model of the profession began to be built in urban craft corporations. The “*metier*” or function, a term used since the middle ages by medieval corporations, presupposed a means of learning and a social pertinence. This model began to be the target of attacks at the end of the eighteenth century because it seems an obstacle to the transformation and rationalization of the manufacturing work methods. It defines skill as “the ability to accomplish a task or a set of tasks, in accordance with certain standards required by the organization”, involving theoretical knowledge and personal skills.

The use of the notion of competence began to appear when companies had the need to recognize people's competences, regardless of the job they were occupying. The emergence of the model Dand Competence represented a new moment, whose practical bases are still being developed. Many alleged competency management systems are still only modernized forms of the workstation model.

For Brandão (1999, p. 22) The meaning of the word competence has been expanding since the end of the Middle Ages. There was, firstly, a legal meaning: "Faculty attributed to someone or to an institution, to appreciate and judge certain questions". It later emerged an extension of the concept: "Social recognition on the ability of someone to pronounce, regarding a specific subject".

Skills Type

Nordhaug (1998, p. 10), classifies skills in: technical, interpersonal and conceptual. The technical competencies are related to the methods and processes, designed to conduct a specific activity and skills to use tools and operate equipment related to an activity. Interpersonal skills are human behaviors and interpersonal processes, empathy and social sensibility, communication skills and capacity for cooperation. The conceptual competencies are analytical skills, creativity, efficiency in solving problems and the ability to recognize potential opportunities or problems.

INFORMATION AS RESOURCE OF ORGANIZATIONS

Information Economics

Economic theory is concerned with answering two fundamental questions: the determination of how scarce resources are distributed in a complex society; The way in which these resources are distributed that maximizes the benefits to society. Many analysis models have been developed to answer these questions. The term economics of information began to appear in the economic literature from 1960 onwards. In the information sciences, it was initially related to the evaluation studies. More recently, in the 1980, the cost and Effectiveness of information services approach was included, followed by discussions on the value of information for the user and the productivity of information in Work.

The literature on the subject has been published in a more pronounced way in the United States and Great Britain. The study Dthe information economy presupposes the definitionDthe concept Dand information. In a popular sense, information is understood as any clarification that can be given to a person about what she asks. Information feeds knowledge in new situations. The information may be shared, but the knowledge is personal and is only shared if the knowledge holder wants to.

Primary data from credible sources are collected, processed, processed, sorted, transferred, evaluated, and so on. The information is viewed as a product or even as a resource, but the information is a unique resource, of specific nature and very characteristic characteristics. Cleveland (1982) characterizes the information as follows:

- **Information is "human"** - there is only information through human observation;
- **The information is multipliable** - the more we use it, the more useful it becomes; The basic limit is the biological age of people and groups;

- **The information is replaceable** - it can replace other features such as money, people, raw material, etc. For example, the accumulation of information in area D Automation replaces several million workers annually.
- **The information is transferable** - the speed and ease with which the information is transferred is a considerable factor for the development of all areas of knowledge;
- **The information is diffusive** - it tends to become public, even if our efforts are in the opposite direction;
- **The information is shareable** - the goods can be exchanged, but, in the exchange of information, the seller continues to possess what he sold.

The study of the information economy has often used classical economic theories. However, during practical studies and experiments, some special features of the information have emerged:

- The information products have value, but their benefits depend on the ability of those who exploit them;
- The information is not consumed with the use; Only time sometimes makes information unimportant;
- Information is not a constant, that is, usually it cannot always be quantified;
- Information is an abstraction, that is, it is produced, disseminated, accumulated and used for different objectives and purposes. This feature causes a lot of confusion, for example, when someone estimates the value of the information according to what the other is willing to pay for it;
- New information is usually produced with public resources (basic research), and these costs are usually not imputed for the purpose of defining the market price;
- The real benefit of the information is difficult to measure because it is limited to its use, which is impracticable.

The study of the information economy becomes problematic in the face of these information characteristics. The information economy is, however, becoming an important object of research in the information sciences.

Economic analysis plays a key role in assessing the cost-benefit ratio. Cost-benefit analysis is a technique that seeks to determine and evaluate the costs and social benefits of investment to help decide whether or not a project should be implemented. The emphasis on costs and social benefits distinguishes it from other investment techniques. The technique tries to measure losses and gains, in terms of economic well-being for society, both in evaluating a project itself and in the different options of taking it forward. The cost-benefit analysis helps decision making when it seeks to answer the following questions:

- How much should the organization invest in information products and services?
- Of the current costs of the organization, how much is it to refer to information services and other activities?
- Are the resources currently budgeted for the information appropriate or should it be altered?
- How are resources allocated between the different information services?
- Are investments in information services successful or should they be changed?
- What use has every project of information service?
- How are prices given to information services?
- How can the production and dissemination of information be supported or taxed?

- Are the costs appropriate to the organization's management and investment plans?
- What measures are necessary to monitor the performance of information services?

Some investigators have criticized a lot and indicated flaws in the generalization of the cost-Benefit analysis of information. They affirm that both the scientists of the information sciences and the economic sciences have doubts about the possibility of measuring the value of the use of information. However, the cost-benefit analysis is potentially appropriate for decisions on the allocation of resources in social welfare projects, such as in libraries and information services where the benefits are not always direct and Tangible.

Companies have undergone a phase of transition from an industrial economy to an information and knowledge economy, that is, an environment where information adds value to products and services. The companies that have been used to succeed, are losing ground for more agile competitors in the use and information management.

In this context, the information is treated as a strategic resource that needs to be administered daily, with the same attention to the human and financial resources of the organizations.

The economy is growing in the production of goods, services and information, and can be generally characterized by the following assumptions:

- The perception that the industries and the economic sectors will be dependent on a workforce that has access and can work on the information;
- The recognition that information needs to be organized, structured, systemized, stored, managed and easily accessible;
- H recognition that the skills of creation, search, analysis, evaluation and interpretation of information are essential for individuals and groups, both inside and outside organizations;
- The perception that information needs (what information?) become increasingly complex and dependent on different and multiple sources, whose correct evaluation and quality is a crucial factor for decision – making processes;
- That the growing development of information and communication technologies challenges both the competences of the Laity, and the Information Professionals, in terms of their understanding, mastery and management;
- Recognition that the information sector is a substantial part of the economy of the country and the World.

Economic Profitability

For economics the need is the sense of a certain lack attached to the desire to be eliminated. The need, therefore, is the desire for a means capable of preventing or ceasing an unpleasant sensation or of provoking, preserving or ameliorating a pleasant sensation.

The media that serves people to meet their needs is designated by economists as goods. A good, all that we recognize as capable of satisfying a need regardless of any other judgment (egg moral judgment). Goods can be classified in several ways. The first thing that interests us is the one that distinguishes the so-called free goods (for example, the air we breathe, water) from economic goods. An economic good is characterized by its scarcity and is one that exists in smaller quantities than required, given the felt need.

The utility of a good refers to the quality and ability of that good to meet the needs that are appropriate for that good. The utility of a good is the ability of that good to satisfy the needs that are subjective

sensations, it follows that the same good may have different utility for different people, depending on the intensity with which they can experience or feel the needs that can be met, for this good.

Closely associated with the concept of utility is the concept of “economic value”, of which we can say that it is the quality of everything that is given importance, because it is considered worthy of esteem. Thus, the value of a given good also depends on each person, since each one may feel distinct appreciation for that good.

Organizations are seeking economic return by selling their products or services. In a competitive environment, an organization can perform better than its competitors because it has better characteristics or because the organization makes better use of its distinctive skills (Penrose, 1959 p. 54). A distinct competency is defined as a distinct qualification, complementary assets, and organizational routines that together enable the company to coordinate a specific set of activities that provide the basis for competitive advantage.

Competitive advantage is referred to as economic profitability (Porter 1980). Subsequently, the resource base views the strategy as an ongoing search for profitability. Profitability is then defined as the excess return on a resource that owns an opportunity cost (it is the return that can be generated when put into alternative use or the price at which it can be sold (Grant, 1991). In other words, profitability can be measured as a normal financial return.

In order to differentiate possible sources of profitability, some types are distinguished. For example, the return may be accomplished by:

- Superior ability to manage and coordinate resources;
- Possession of a valuable resource that is rare;
- Government protection when barriers to entry for new competitors are high;
- Business execution risk in uncertain and complex environments;
- Make better use of the organization’s resources, any of its physical assets and human capital.

The resource base is an attempt to explain why organizations differ in resources and capabilities and how these differences can lead to sustained profitability positions, producing superior financial returns. Core resources, therefore, serve the purpose of explicitly focusing on the role of resources and the capacity of organizations, such as strategy origin and organizational performance. This exploration of the relationship between resources, competition, and profit includes, among other issues, the role of imperfect information in creating profitability differences between competitors (Grant 1991, p. 3).

Information Profitability

Information is a complex concept, ubiquitous since the emergence of life and inherent in any evolutionary process and thus served and continues to serve as a milestone for reflection in both biology, physics, psychology, management, linguistics, as in various other Branches of science.

The power of information resulted from the development of information and communication technologies during the twentieth century, as occurred two centuries ago, with the concept of energy, a key factor of the industrial revolution.

The imperfections of information are some of the competitive imperfections that collide with the economic ideal of the perfect market. The perfect market is characterized by countless customers and suppliers of homogeneous products, whose pricing mechanism determines the most efficient market

organization. Looking at the information, all customers and suppliers are fully and perfectly informed about all relevant aspects of business transactions.

While the ideal market serves as the most important neoclassic economic theory, the appropriations of contemporary economic theories tend to allow this, contrary to the appropriation of unreal theories. Therefore, we assume that in the perfect market, customers and suppliers are perfectly informed, but that is a myth. For this reason, it is proposed that markets are characterised by imperfect competition and that the imperfections of information are an important trend.

The amount of return that an organization can perform depends on the cost of resources, the cost of acquiring new resources, and their economic value, when the products are sold out. In the competitive markets, customers and suppliers will have the same expectations, about the value and cost of resources and products.

Consequently, vendors never sell a resource or their product, if the total value is not reflected in the price, or customers will pay a higher price than the cost. In these circumstances of the perfect market, the strategy can only produce the normal return, as opposed to the return mentioned above, namely profitability.

Information Imperfections

To understand how economic profitability can be identified and appropriated by strategic information, it is through knowledge of the origin of the imperfections of information. The costs of economic transactions (CTE) describe these origins and three types of information imperfections resulting from them.

The theory of transaction costs assigns two behavioral appropriations to man: the limits of rationality and opportunism. We assume that men are intentionally rational, but they are limited by that. The limits of rationality are beyond the inability of the human brain. This involves neuropsychological boundaries of one skill, on the one hand, and on the other, the limits of language. Physical boundaries take the form of value and storage limits of the power of individuals to receive, store and process information, without error.

Human cognitive abilities are generally insufficient to understand particularly complex tasks, to recognise the need for pertinent information and to make all relevant information. It explains the limited rationality of the rational behavior of information. Instead of a thorough search for relevant information, the only decision maker tries to obtain a subjective satisfaction, the level of incomplete information. This type of behavior is known as “satisfactory”: looking for a solution that meets the aspirations of decision maker level and therefore the acceptable.

Human beings are not only rational; they also assume some opportunistic behavior. Williamson (1975) describes opportunism as “the pursuit of self-interest, with cunning” involving “disbelief of threats and opportunities” in order to accomplish the individual advantages. These advantages are also appropriate to “select and distort the discovery of information or discredit the opportunities that lead to the future” (Williamson, 1975, p. 26). The claim is that although not all humans are comportandm opportunistic, it is difficult to predict in advance whether they will behave or not, as such.

These two types of behaviors reflect the relationship between vendors and customers. The combination of opportunistic and rational behavior is the main cause for the three types of information imperfections in the transaction market:

- **Asymmetric information** - an asymmetric distribution of Information, from the parties involved in a transaction, causes a strategic opportunity. The critical impact of information on optimal allocation of risk is not merely its presence or absence, but the inadequacy of its economic agents. Thus, it joins two conditions in which the information asymmetry provides a strategic opportunity in the transactions:

- I. High costs for achieving equal information;
- II. Propensity for opportunistic behavior. For other words, asymmetric information occurs, when one of the parties has information that is unknown to the other and of hard obtaining for the other part. You have an opportunity to explore this advantage of information through strategic alternatives.

Asymmetric information may result in a favorable situation for suppliers or customers, depending on what has this information. The opportunity is caused by hidden information for the transaction. One of the parties in a business transaction is better informed, about a relevant variable than the other. It is the invisibility of this private information that constitutes the essence of the imperfections of information and introduces the risk to the other party.

Considering the possibility of opportunistic behavior, the part that has hidden information, has no incentive to disclose it, if it is harmful to it. As a result, any supplier entering the market with a product or service that is particularly suitable for a specific market segment, with the main benefits for competitors benefiting from the hidden information. The imperfections of information are known as enemies.

- **Ambiguous information** - Information ambiguity in a business transaction can cause a strategic opportunity. Although in the case of complete information, different interpretations about them may occur. As a result of opportunism, these representations can be opportunistic in the sense that it can lead to a single advantage for any supplier or customer.

The strategic opportunity for one of them is discovered, when such opportunistic interpretation is not recognised by the other and results in:

- i. The customer will pay a higher price for a product;
- ii. Supplier availability to offer a low-price product.

As a result of this opportunistic behavior, the part with opportunistic interpretation has no incentive to share this information if it becomes a disadvantage to it.

- **Incomplete information** – the strategic opportunity for incomplete information is closely related to the assumption of rationality. The limits of rationality are certainly interested in expanding the limits of rationality achieved, in conditions of uncertainty and complexity. In the absence of any of these shares' ownership terms can be quite specific to this principle.

In an environment characterized by much complexity and uncertainty, the possibility of certain events occurs quickly, and become numerous. In these circumstances, it is impossible for humans to acquire and analyse comprehensive information relevant to strategic decision making. As explained earlier, this inability leads to satisfactory behavior. The opportunity for incomplete information occurs when

a customer is not fully informed about the range of possibilities of the transaction, about the products offered and vice versa.

Therefore, a client that allows an incomplete comparison of the vendors and their differences, can initiate a transaction with the worst vendor. For the supplier this opportunity can be exploited for the creation of a brand.

Quality of Information

Not all information is good, one is better than another. It is therefore necessary to assess its quality. The criteria for assessing the quality of information are as follows:

- **Relevance** - the information must be *relevant*, that is, it must relate to the facts, be available and be important to the person who requires it. The information will help people make decisions.
- **Opportunity** - information should be *timely*, that is, to be available to the right person at the right time. If, for example, a person doesn't know the train's departure time, they risk losing it.
- **Accuracy** - The information must be *accurate*, this means that if the information is not accurate, it loses interest;
- **Reduction of uncertainty** - just think about taking decision with and without information; good information reduces uncertainty. Good information involves the difference that *makes a difference*;
- **Element of surprise** - information can be used to obtain competitive advantages;
- **Accessibility** - Information is only useful if people have access to this; *Accessibility* is within reach of those who can obtain the information, in time to being used efficiently and in the form that makes them useful. Electronic storage makes information more readily accessible than pencil and paper technology.

RELEVANT ISSUES

Information Needs

To manage the production is necessary information about each worker, his/her tasks, working hours, productivity, equipment, product and its characteristics, etc., but is not yet a factor of production. With high productivity and low costs, the market becomes a salesman instead of a producer, consumers become increasingly demanding increasing competition and begin to influence production: product quality and preferences of Consumers, give rise to the economy of services, on the counterpart of the economy of the product.

In this economy, there are three factors influencing production: the event (or eventual situations), communication and service. Production begins to target events; Which does not conform to the regularity of mechanical production. Whether to cater to different customers with their specificities, be it to solve the normal production problems. Human activity is now due to irregularities, novelties and innovations. In this way, information gains paramount importance in production. You can't handle events and innovations without information and knowledge about an ever-increasing set of operations. Communication also becomes a primordial factor because problems become more complex, requiring more than one area of knowledge to solve them. It is necessary to use the information efficiently so that there are no communication problems, that is, the information becomes one of the factors of production.

Identification of Informational Competencies

For identification the informational competences, can be taken as basis, the various typologies approached previously and, from them, select the specificities. The interpersonal informational competences and the conceptual informational competences may be related to the skills of mediation of the professional who works with the information to make the meeting between information and your user.

In the typologies of Fleury & Fleury (2001) Organizational informational competencies are the set of individual informational competencies embodied in organizational processes, in order to construct specific competences related to the information activities essential to the organization. The key competences of Prahalad & Hamel (1990) could correspond to informational competences developed in an organization with the specific objective of differentiating or improving the competitiveness in the market.

In the typology of Zarifian (2001), General and professional knowledge (references of a given professional universe) are linked to the characteristic training of an information professional and the background informational competences (acquired in Educational situation and formalized in cognitive and behavioral achievements necessary to address the categories of problem situations) are linked to what will be developed or mobilized in specific organizations or activities, to solve the specific informational problems faced in each case.

Four categories of key management competencies can be identified:

- **Relational competencies** - work productively with others;
- **Troubleshooting skills** - identify, formulate and execute creative solutions to problems;
- **Capacity-building skills** - recognizing the need to change and undertake change;
- **Communication skills** - communicate effectively and efficiently.

The skills for problem solving are perception capabilities, capacity planning and organization, and capacity to make decisions. These competencies include the selection of information, the mastery of appropriate methodologies and tools for the treatment of this information, with a view to generating appropriate results, with effectiveness and efficiency. Communication competence involves oral and written communication, focusing on the mastery of communication processes, which involves language, the ability to understand and transmit ideas.

For the purpose of identifying informational competences, it is considered that the competences linked to information are related to the informational process, process that, studied by the information sciences. These competences relate to information and communication technologies, with the cycle and analysis of information. These are competencies that permeate the business processes, the management processes and the various technical processes, as well as different parts of the same organization. Other components of informational competence should be identified in the analysis of situations, by the expression of the initiative, responsibility, transformation and mobilization of actors and sharing.

For any organization the problem is to define the model of competencies, that is, how to organize and structure the information to facilitate communication, given the complexity and turbulence of the world of work, since the communication became a primordial element. The information is what specifies, selects or singularizes the requests, in view of successful professional conduct. What matters in this professional situation is the pertinent information about what someone requests in view of the action, allowing the individual to situate in the Environment and act effectively.

Informational Competence

To deal with informational competencies the following concepts were chosen:

- **Competence** - is "... A knowing act responsible and recognized, which implies mobilizing, integrating, transferring knowledge, resources, skills, which add economic value to the organization and social value of the individual "(Fleury & Fleury, 2001, p. 21). The main attributes of competence are the initiative, Responsibility, Practical Intelligence, acquired knowledge, transformation, diversity, mobilization of actors and sharing (Zarifian, 2001 and 2003).
- **Professional competence** - it is related to people or work teams, integrating technical, cognitive, social and affective aspects related to work (Brandão, 1999, p. 28). It comprises knowledge, skills and attitudes or behaviors that will allow the organization's development, in fulfilling its mission (Dutra, 2001);
- **Organizational competence** - is the *savoir-faire* of the company in a particular domain, which originates and sustains itself by professional competences, allied to the organizational processes and other resources, or the ability to combine, mix and integrate resources into products and / or services (Fleury & Fleury, 2001, p. 23). They include the skills of the organisation and its processes, skills in techniques and forms of work, service skills and social skills;
- **key competence** - is the set of skills and technologies whose brand of authenticity is integration. They represent a perceived value by the customer, a differentiation between competitors, an expansion capacity (Hamel & Prahalad, 1995, p. 233-241). They are above all a distinctive and unique factor that marks an organization or activity.

Based on the above concepts, informational competence can be defined as the set of professional, organisational and key competences that may be linked to the profile of an information professional or an activity intensively based on information. This competence can be expressed by the *expertise* in dealing with the informational cycle, with information technologies and informational contexts.

The competences information is mobilized in working situations be one of the requirements of the professional profile necessary to work with the information, regardless of the type of professional or activity. They are competence that premise the business processes, the management processes and the technical processes various parts of the same organization or activity. It would be desirable that informational competences were part of the list of competences of the most varied professionals, activities and organizations.

Information Professional

The professional expression of information, in a certain way, has already established itself as a reference to designate, in a generic way, those who work in the area of science of information, although this expression is also used in other areas, as is the case of communication, in which journalists and reporters are often called information professionals. Access to information or facilitating this access is the objective of these professionals, who serve users, beneficiaries of this access, divided into groups with different characteristics and demands of information.

There are many denominations used to refer to professionals who deal with information: Information Professional, information agent, knowledge professional, knowledge worker, archivist, librarian, museologist, communicator, among others and whose relevant activities are linked to the process of

generation, dissemination, recovery, management, correction and use of information. They are professionals whose denominations in the labor market indicate a strong interaction of skills and technical knowledge and management available in the area of the professionals of the information and other areas, such as Education, Marketing, History, Administration, Economics (web designers, content engineers, information architects, among others).

According to Tarapanoff et al (2002), information scientists are the information mediators, since they act between the digital world and the real capacity of understanding the information receivers, guaranteeing the effective communication and the satisfaction of the informational needs of users of this technology. They are professionals who know how to use information technologies; dominate at least one foreign language (English) and have knowledge of Web and tools for connectivity.

The informational cycle identifies all phases of work with information: determination of information needs, sources, collection, processing (information and communication technologies, as support) / treatment (pencil and paper technology), the use and distribution of information. The informational context is the context in which the informational cycle takes place and influences its flow and its characteristics: technological information, business information, scientific information, etc.

Information professionals' skills profiles can be summarized as follows:

- Domain of more than one language, (English required);
- Communication capacity;
- Good interpersonal relationship;
- Management knowledge, (mainly the strategic management of information for the management of organizations);
- Organizational culture;
- Leadership capacity;
- Ability to filter information by adding value to products and information services;
- Ability to work the abstract (teaching / learning of informational tools, management, planning and research), in which the knowledge of information technologies and communication in the user's perspective, are important, but not determinants;
- Ability to assess, plan, sell and operate local information communication networks in institutions;
- Ability to manage information units and implement information management programs, including the Informatization;
- Ability to search, prepare, summarize and edit information of a scientific and technical nature;
- Ability to direct the writing of scientific journals in publishing companies;
- Ability to organize (acquire, register, retrieve) and distribute the information in its original form or as elaborate products from it.
- Ability to perform social functions; education and mediation. The education relates to literacy in information, and the second, to the animation of collective intelligence. Educating oneself and educating others to the information society is one of the great challenges for information professionals and an important step towards the formation of informational culture in society and, eventually, collective intelligence.

CONCLUSION

For the information to be used, it needs to be valuable. Today people and managers are flooded with information. This requires a process of filtering and conscious management to identify what are the relevant information (strategic information) to support decision making (strategic).

The information adds value when it allows people and managers to identify opportunities (strategic and threats), detecting trends or potential problems. The information adds value to the business, when its analysis / interpretation identifies new ways of doing business, new products and or services (product development or diversification).

The relevant information affects the success of organizations, since they are a strategic resource of high added value, because they allow managers to be constantly attentive / informed about the alternative scenarios (external).

Although there is consensus on the importance of information, the available literature mainly covers the electronic treatment of data and reflection. The effective use of information has not grown in the same proportion as technology, which itself is unable to provide the information that people, and managers need.

Future Research Directions

The study of the role of information in the formulation of the business strategy, the information sciences recognize a gap in the set of theoretical publications with potential for enrichment and exchange of interdisciplinary knowledge among the sciences of Information and other fields of knowledge that focus on the strategy.

The scarcity of works focused on these topics in the information sciences can be an indicator not only of the potentiality of spaces to deepen the interdisciplinarity between information sciences and other areas of knowledge, but also the Potential of niches for unpublished and original works in this area of knowledge.

By identifying the competences of some professionals who exercise any activity in an organization and by comparing these activities and specific competences of so-called information professionals, it is likely that there are some "Coincidences", especially if the studied activity intensively uses the information. These "coincidences" are called informational competencies.

KEY TERMS AND DEFINITIONS

Informational Competence: Can be defined as the set of professional, organizational and key competences that may be linked to the profile of an information professional or an activity intensively based on information. This competence can be expressed by the *expertise* in dealing with the informational cycle, with information technologies and informational contexts.

Key Competence: Is the set of skills and technologies whose brand of authenticity is integration. They represent a perceived value by the customer, a differentiation between competitors, an expansion capacity (Hamel & Prahalad, 1995, p. 233-241). They are above all a distinctive and unique factor that marks an organization or activity.

Organizational Competence: Is the *savoir-faire* of the company in a particular domain, which originates and sustains itself by professional competences, allied to the organizational processes and other Resources, or the ability to combine, mix and integrate resources into products and /or services (Fleury & Fleury, 2001, p. 23). They include the skills of the organization and its processes, skills in techniques and forms of work, service skills and social skills.

Professional Competence: It is related to people or work teams, integrating technical, cognitive, social and affective aspects related to work (Brandão, 1999, p. 28). It comprises knowledge, skills and attitudes or behaviors that will allow the organization's development, in fulfilling its mission (Dutra, 2001);.

APPENDIX

Information Professionals ' Skills Profiles Can Be Summarized as Follows

1. Domain of more than one language, (English required);
2. Communication capacity;
3. Good interpersonal relationship;
4. Management knowledge, (mainly the strategic management of information for the management of organizations);
5. Organizational culture;
6. Leadership capacity;
7. Ability to filter information by adding value to products and information services;
8. Ability to work the abstract (teaching/learning of informational tools, management, planning and research), in which the knowledge of information technologies and communication in the user's perspective, are important, but not determinants;
9. Ability to assess, plan, sell and operate Local information communication Networks in institutions;
10. Ability to manage information units and implement information management programs, including the Informatization;
11. Ability to search, prepare, summarize and edit information of a scientific and technical nature;
12. Ability to direct the writing of scientific journals in publishing companies;
13. Ability to organize (acquire, register, retrieve) and distribute the information in its original form or as elaborate products from it.
14. Ability to perform social functions; Education and mediation. The education relates to literacy in information, and the second, to the animation of collective intelligence. Educating oneself and educating others to the information society is one of the great challenges for information professionals and an important step towards the formation of informational culture in society and, eventually, collective intelligence.

A Primer on Q-Method and the Study of Technology

Stéphanie Gauttier

Grenoble Ecole de Management, France

INTRODUCTION

Q-method has been invented in 1935 by William Stephenson in order to capture individuals' operant and subjective points of view on a given topic, based on the use of concurrence theory and a forced distribution matrix. Essentially a qualitative research method, it is often qualified of quali-quantology or mixed method due to the use of a q-factor analysis to examine the data.

Q has been largely overlooked by researchers interested in the study of technology. For instance, in Information Systems (IS) research, i.e. research focusing on digital technology as a socio-technical artefact, only 20 papers can be retrieved (Gauttier et al. 2016; Gauzente, 2013). Yet, Q-studies have been published in major journals in the field (among others: MISQ, I&M, CAIS, JIT, OMEGA), indicating its potential for research related to technology. The fit between Q-method and IS topics has been mentioned several times in the literature (Gauzente, 2013; Thomas and Watson, 2002; Kendall and Kendall, 1993; Dos Santos & Hawk, 1988).

This entry describes Q-method and how it can be applied to IS topics to yield new insights. It provides a description of the current use and potential uses of Q in IS research as well as practical advice on how to set up a Q-study. Areas for future research are outlined. It is targeted towards any researcher interested in capturing attitudes to and experiences of technology, as well as those looking for methods to inform the design of technological artefacts and their evaluation.

The reader will notice that the different elements at play during a Q-study are designated as Q-(study, set, factor analysis, etc). The presence of the Q letter could be omitted, and other words could be used. However, the omnipresence of the letter Q in this text is consistent with the vocabulary used by Q-methodologists in publications. It also serves as a reminder to the reader that in this chapter every notion should be interpreted in regard to the Q approach and intentions, and not to the R logic with which the reader might be more familiar. Indeed, in contrast to positivist approaches and the use of R-methods, Q-method considers the self-referent subjective experience of reality (or here technology). It does not aim at a generalizable objective view of a phenomenon, nor does it look at the relationship between variables composing the phenomenon. Q-method identifies the shared perspectives on a given topic between individuals (Watts and Stenner, 2012).

BACKGROUND

Q-method was developed by the psychologist Stephenson (1935; 1953) as an approach to capture people's operant subjective views of phenomena. Subjectivity is conceptualized as what '*emanates from a particular vantage point*' (Brown, 1993). Operancy refers to the fact that these views drive individuals'

DOI: 10.4018/978-1-7998-3479-3.ch120

behaviors. It is a method suited to the identification of the drivers, barriers, and structuring elements of behaviors and experiences.

Q-method rests on two important pillars. One is theoretical and refers to concurrence theory, the other is methodological and uses Q-sorting procedure and Q-factorial analysis (Gauzente, 2010). First, the concurrence theory posits that meaning is dependent upon context and therefore not given *in abstracto*. The concurrence can be defined as the volume of available statements on a topic and is '*the common coinage of societies large and small, and is designed to cover everything from community gossip and public opinion to the esoteric discussions of scientists and philosophers*' (Brown, 1993). Meanings exist for each individual and vary depending on circumstances, but can also be shared with others, thus making interpersonal communication and interpretation possible.

The first step to conduct a Q-study is to generate these meanings. These constitute the Q-sample.

Then these meanings are ranked onto a Q-sort grid, i.e., respondents rank-order assertions according to the degree with which they represent their subjective view of one topic. The forced ranking distribution means that only a small amount of assertions can be selected as highly positively or negatively representative. The majority of meanings will be neutral. This process forces respondents to choose and structure their point of view. The respondents are designated as the P-sample. The result of the Q-sorting process by the participants is a Q-sort. The participants are invited to comment on their Q-sort and reveal how they interpret the elements of the concurrence as well as their own subjective point of view as revealed through the process of the study. Then, a factor analysis is performed to process the Q-sorts. Instead of individuals, assertions or statements are analyzed. In other words, the correlation matrix relies not on assertions but on individuals. This procedure is called Q-factor analysis. As a result, one identifies Q-factors, which are designated as view, i.e. shared views amongst participants. The views shouldn't be assimilated to groups of people as in typological approaches. The views are not a statistical representation of groups in the general population. Rather, they are shared operant views and interpretations of a topic.

Q-method is used in many different disciplines such as political sciences (on questions linked to evaluation and decision-making, but also to capture the structure of individuals' political views), education (capturing learning experiences), health studies (capturing carers' and patients' experiences), leadership studies, but is currently under-represented in IS research.

FOCUS OF THE ARTICLE

The study of technology, as pursued in IS research, has traditionally adopted a positivist lens. In spite of a turn recognizing the potential of qualitative interpretive approaches grounded in social constructivism, sociomateriality (Scott & Orlikowski, 2013), or phenomenology (Boland, 1986) to study technology, the share of such research in major IS publications is still low compared to positivist studies. One can cite two main barriers to the diffusion of interpretive research in IS. First, interpretive research refers to a complex epistemological positioning, with a plethora of traditions and approaches that the researcher must choose from. These approaches are often described at a philosophical level, and little guidance is available to implement them. Second, interpretive research can be seen as biased by positivists: the process of interpretation seems to depend on the subjective and hidden choices made by the researcher and does not offer the possibility to reproduce the process of analysis. Q-method allows overcoming these barriers (Gauttier, 2017), while identifying what drives and structures individuals' relationships to technology.

1. Epistemological Positioning

Q-method is a qualitative method, which has been positioned as phenomenological and interpretivist.

According to Shinebourne & Adams (2007), Q can be qualified of phenomenological as it seeks meaning *‘through exploring subjective accounts of phenomena from participants’ perspectives, attempting to identify broad categories and common themes and a commitment to a collaborative engagement with participants.’* The classification is controlled by the participants as they rank and give meaning to assertions, while the role of the researcher is to exert discretion during the processing of the data (see 2.3) to ensure the views of the participants are correctly represented in the results. The views are given from the participants’ perspectives, interpreted by the researcher.

2. Carrying Out a Q-Study

Descriptions of the process of a Q-study have been given numerous times in the literature (Brown, 1993; McKeown & Thomas, 2013; van Exel and De Graaf, 2005, etc). Details are given concerning 1) the formation of the concourse and Q-set; 2) the administration of the Q-study; 3) the data analysis.

2.1 From Concourse to Q-set

The concourse can be of three different types:

- 1) Naturalistic, i.e. gathered for the purpose of the study at hand through interaction with individuals during focus-groups or interviews (Brown, 1980). The individuals that helped to generate the concourse can be the participants of the subsequent steps of the study, although it is not mandatory.
- 2) Ready-made, i.e. already constituted in the literature or obtained through a literature review or constituted by a series of experts.
- 3) Hybrid, i.e. the researcher completes a naturalistic concourse with elements found in the literature.

There is no type of concourse superior to another. Rather, the researcher must choose to form the concourse in the way that is the most appropriate for the study at hand.

The meanings included in the concourse can then be expressed in the form of pictures, textual statements, and sounds. One could also consider using smells. The vast majority of Q-studies are performed using textual elements. Pictures are used to interrogate children’s points of views, to study arts, or in human-computer interaction to look at preferred designs (for instance such an approach was implemented by the International Society for the Scientific Study of Subjectivity in 2015 to survey members’ preferences for the new website).

The concourse constitutes the available list of elements on a topic, and as a consequence, it can be rather large. There is no magic number on the number of assertions to keep. Q-studies with as many as 1575 statements - even if broken down into smaller sets to administrate the study (Hilden, 1958) and as few as 14 statements (Manera & Wright, 1981) have been conducted, never mind their relevance. However, it is noteworthy that a bigger amount of statements decreases the chance of having random correlations. At the same time, one should consider the format of the assertion and the capacities of participants: children, patients with serious conditions, elderly, might not be able to rank as many assertions as other populations. Brown (1980) recommends a set of 40 to 50 assertions. Sets of 24 statements have been discussed as potentially not enough to cover the nuances of points of view even though they might be

enough for a given topic (Q-method listserv, 2017). In essence, the researcher is responsible for making sure the participants can express their point of view through the assertions proposed while maximizing the quality of data collection. Indeed, given that the participants have to consider these elements holistically to rank them in the Q-sort grid, it is necessary for the researcher to think of the maximum number of elements that can be kept for the final sorting procedure (the Q-set) so that participants can handle the amount of assertions and rank them. Different strategies can be adopted to ensure the representativeness of the Q-set: one can gather the concourse and transform it into a Q-set with participants through focus groups (naturalistic approach); or one can pilot the Q-set and ask participants whether they think the concourse allows them to represent their point of view, then refine the Q-set in accordance to the answers before administrating the Q-study.

The Q-set must avoid redundancies. As the sorting occurs using a scale from positive to negative, there is no need to keep opposite assertions: if a participant disagrees with the statement “eating ice-cream makes me happier”, (s)he can put it in the negative scale on the grid, eliminating the need for a statement “eating ice-cream doesn’t make me happier”. There is no need to keep statements that carry the same meaning as they would be placed in the same column, putting other statements in higher or lower columns only in an artificial manner and rendering the exercise cumbersome for the participant.

The Q-set might include what is seen as a double-barreled statement in so far as in context and for the participant, it is not double-barreled. For instance, a statement taken from an interview and included in a q-set might seem to be double-barreled, but for the interviewee, it is one statement, one unit of meaning, not two, and therefore can be ranked and interpreted as one statement. Moreover, Brown (Qserv list, 2018a) explains that ‘*The other statements surrounding this particular (double-barreled) statement within Q-sort 1 will provide hints as to the particular connotation of the statement, and it is this that demonstrates the gestaltist principle in Q—that the parts gain meaning in relation to the whole.*’ Each statement takes a particular meaning because of how it relates to others, lifting ambiguity on how it is to be interpreted.

In order to assess the understandability of the Q-set and check for redundancies, it is possible to pilot the Q-set before administrating the studies.

2.2 Administrating Q-Studies

Five elements need to be taken into account when one administrates a Q-study:

- 1) The selection of participants: Q-method is, in essence, a qualitative method as it looks at the subjective. It can be used with a small number of participants (Van Exel & De Graaf, 2005). Single case studies are even possible (Stephenson, 1974), as Q aims at representing the point of view of individuals in an extensive manner. In Q, the selection of participants is purposive (Brown, 1980): they are chosen because of how they relate to the topic and/or question researched, i.e. one might want people with specific experiences or characteristics to participate. For instance, in IS research individuals with experience of a specific technology (Gauttier et al., 2016), or individuals who identify themselves with given forms of technology use (Gauttier & Gauzente, 2018) might be selected. Brown (Q-method listserv, 2018b) suggests designing a p-set matrix. This matrix can include key characteristics of participants pertaining to the object of the study, and characteristics pertaining to participants as individuals. It allows designing a participant selection strategy. For instance, to study the drivers and barriers acceptance of technology, one can consider levels of use so that the first line of the matrix is composed, for instance, of a) heavy user; b) occasional user;

and c) non-user. Then, the researcher might want to integrate considerations of gender, adding another element to the matrix, which takes a 3x2 structure.

Assessing the representativeness or weight of each view identified through the Q-factor analysis is not the objective of Q-method. Such a typological approach would be a misunderstanding of the underlying logic of the method. The views have value as they signal the existence of hindrances and drivers of behaviors, with these hindrances and barriers being operant and not only plausible. Comparing views is thus possible, no matter how many people share the view. (McKeown & Thomas, 2013).

- 2) The conditions of instruction: Depending on the topic of the study, the researcher may opt for a simple design requiring the individual to sort the assertions only once from his/her point of view. Other designs can be implemented. Firstly, one can modify the number of times one proceeds to the sorting so as to see how one's point of view evolves over time, given that some form of intervention is going on. Secondly, one can ask participants to sort the same assertions but looking at various angles of the topic. Thirdly, one can ask participants to proceed to the Q-sort from the point of view of someone else.

For instance, Gauttier and Gauzente (2018) asked participants to proceed to Q-sort 9 times to express their view on mobile technologies overall, different technologies, the point of view participants attributed to their parents, and the point of view participants would attribute to future/children's generations, and then general opinion again.

One could also imagine that instead of having individual Q-sorts, a group could be asked to proceed to Q-sorting.

- 3) The design of the forced distribution matrix: The matrix that will be used to proceed to Q-sorting follows a (quasi) normal distribution, allowing participants to place a few assertions to the extreme, and then more and more, to reach a peak in the middle (see Figure 1). The number of cells in the matrix must match the number of assertions. Recommendations about how to build the scale have been given by Brown (1980, p.200): *'As to the range of the distribution: naturally, the larger the number of statements, the wider the range of available scores should be. As a rule, Q samples smaller than N == 40~can safely utilize a range of +4 to -4; from 40 to 60, a range of + 5 to - 5 is generally employed; beyond 60, +6 to - 6 is not untypical, although there are few occasions for a wider range to be utilized since Q samples exceeding 60 are rarely required; most Q samples contain 40 to 50 items and employ a range of +5 to - 5 with a quasinormal flattened distribution.'*

Figure 1. Example of a forced distribution matrix

- 4) The choice of medium: Data collection can be facilitated online through the use of specific platforms (at the time of writing, WebQ and Qsoftware are used). Some studies have used Skype to conduct the Q-sort, sending the assertions and grid to the participants in advance. It can also be conducted face-to-face. Key criteria for choice are mainly linked to convenience and access to samples. It is however important that the medium allows following the procedure described below.
- 5) The procedure to follow: Firstly, participants are asked to read through the list of assertions entirely, so they have a holistic perspective of it. Then, participants are asked to look at each assertion again and class it in one of three piles (agree, don't agree, no opinion). This helps participants to get acquainted with the Q-set and to proceed to a first sort of ranking, which should help them when they have to produce the detailed ranking demanded in the forced distribution matrix. Q-methodologists do not record this initial rough classification and participants are allowed to modify this classification ranking, for instance, an 'agree' or 'no opinion' as negative in the forced distribution matrix if they want to. The third stage is, therefore, ranking in the grid. Participants can modify their ranking as much as they want and the researcher records only the last version of the grid that satisfies the participants. All assertions must be ranked, and the grid must be respected. The order of the statements in a column is not important.

Sometimes participants have more assertions they disagree with than ones they agree with, meaning that elements ranked under the longest column are not neutral. This is perfectly acceptable as it still means that the statements going to the middle are not the ones the participant focused on and that drives his point of view. Participants can rename the column if they feel they must to convey their idea. Then, a post-sorting interview is conducted where participants have the possibility to explain how they proceeded to the ranking as well as the subjective meaning they give to the statements. Typically, the participants are asked to explain how they choose the statements that are the most extremes and are asked to summarize their point of view.

2.3 Data Analysis

Data is processed through free software. PQmethod has been validated by the Q-methodologists and used in most studies. Ken-Q has been more recently developed and its validation is still in process.

The data is analyzed through a Q-factor analysis process, which is an inverted factor analysis (Stephenson, 1936) in so far as a Q factor analysis looks for what is common between people, instead of what is common between variables.

Table 1. A representation of Q and R matrixes (adapted from Gauzente, 2013)

Q-Matrix			R-Matrix		
Assertion	Individual A	Individual B	Individual	Assertion 1	Assertion 2
1			A		
2			B		
3			C		

Firstly, one needs to proceed to the factor extraction through centroid method (Brown, 1980) or through the Principal Component Analysis method.

Secondly, one rotates the factors, commonly through Varimax. The rotation can be done according to statistical or theoretical motives. Theoretical rotation refers to rotating the factors so as to choose a solution that can be interpreted and explained, even though it is maybe less satisfying statistically. On each factor, defining factors are flagged, based on factors loading.

Then, one obtains the following data: views identified and how the individual Q-sorts load on each factor, a correlation matrix, a table with eigenvalues and variance, a synthetic Q-sort for each factor (each statement with its place on the grid and z-score), distinguishing statements between factors, consensus statements between factors, and arrays of differences. The analysis can lead to the identification of bipolar factors, with significant Q-sorts that load in positive and negative ways.

It is important that the researcher first analyses each view independently of the others, capturing the nuances in each view, before adopting a holistic perspective looking at differences between them.

SOLUTIONS AND RECOMMENDATIONS

Q-method brings results that are of different nature than the ones of R studies. While R studies aim at giving results that are generalizable and representative of a given population, Q gives a representation of the subjective points of views of participants. The non-generalizable character of the results obtained through Q-method is often understood as a limitation, one which is actually common to other qualitative methods. Q-studies are not subject to any form of validation through replication: they capture individuals' points of view as they are, not attempting at verifying their truthful or objective character (Stephenson, 1988). Another limitation can be seen in the presence of subjectivity throughout the process (designing the Q-set, making choices during the factor analysis, and then the subjectivity of the interpretation). However, the role of the researcher's subjectivity in constructing data is a problem common to many methods. Q offers the advantage of allowing to document this subjectivity at different stages: the criteria used to structure the concourse and the steps followed for the factor analysis can be explicitly formulated. The interpretation of qualitative data is therefore open to contradictory analysis as the whole process is traced (Gauzente, 2013). Besides, Q-method allows documenting the researcher's subjectivity alongside the participant's by using the researcher as a participant (Gauttier, 2017).

The interpretation remains subjective but can be verified for its plausible character as they are grounded in mathematical results (the z-score of the statements, the array of difference for statements between factors). Q-studies are easily reproducible as the Q-set is shared with results (Gauzente, 2013; Gauttier & Gauzente, 2016). Q-method allows reaching a deep understanding of individuals' perceptions of a topic as it respects nuances (Gauzente, 2013), and allows to capture complex relationships between points of views (bipolar factors, negative loadings).

With criteria of transparency and reproducibility of both the data collection and data interpretation stages, Q qualifies as a rigorous research method.

At the same time, Q-method is characterized by a process allowing Researchers to be creative to find new ways to shed light on research topics in a qualitative manner. Q can be used to document topics traditionally tackled by studies of technology. In her recent synthesis on Q-method in Information Systems Research, Gauzente (2013) identifies three types of utilization of Q-method:

- Profile identification and fit evaluation
- Identification of structuring trends as an alternative to Delphi technique
- Deep understanding of attitudes, representations, and perceptions.

Over the last five years, a number of papers applying Q-method to IS topics appeared, making use of the creative aspects of Q. They mainly look at attitudes and drivers of perception:

- Study of non-use (Gauttier & Gauzente, 2018)
- Design evaluation (O’Leary et al, 2013)
- Cultural comparison (Gauttier et al., 2016)
- Exploration of TAM and UTAUT (Laden et al., 2018)

Another group of papers comes to address more methodological issues, suggesting that Q can complement our understanding of previous theories, filling in gaps, as well as capture phenomena so far left in the dark:

- Q to study motivations of non-use (Gauttier & Gauzente, 2018)
- Q to perform single-case studies (Gauzente, 2015), i.e. to provide the extensive description of the point of view on a topic, or technology, of one individual.
- Q as a complement to interviews, increasing the transparency of data interpretation in the context of IS study (Gauttier, 2017)

Given the strength of Q-method and its ability to complement traditional research on technology, its use and development are recommended to IS researchers.

FUTURE RESEARCH DIRECTIONS

Q-method can be used to shed light on topics so far explored with different methods. Q-method can also be the object of further methodological research, of interest to IS researchers as well in order to reinforce the place occupied by qualitative research in the field. Four areas are identified:

- *Complementarity between methods suitable for IS studies and Q*: Studies looking at the complementarity between Q-method and R data (Thompson et al., 2013), Q-method and interview data (Gauttier, 2017), have been conducted. One could investigate the complementarity between Q and other methods such as ethnography data, applied to the study of technology.
- *The phenomenological character of Q-method*: A phenomenological turn was called for in IS in 1986 (Boland) and accomplished only to a small extent. Q could be seen as a way to accomplish this task if one could establish in a more detailed manner how Q can be used best to fit the concepts of phenomenology.
- *The use of Q to document the researcher’s subjectivity* can be explored further. This could lead to use the method in combination with other qualitative methods, as a validation process, which could reinforce the acceptability of qualitative research overall in the field of IS.
- Further research could explore topics through different senses, using *sounds, picture, text* to question technology, opening a new way to research the relation to and experience of technological artifacts.

CONCLUSION

This chapter showed that Q-methodology offers a large potential to be explored by IS researchers. The versatility of Q allows designing creative and innovative approaches to data collection, which can be applied to any topic. Through its flexibility, the method can allow to yield new qualitative insights on trends, fits, and perception of technologies which can allow overcoming gaps presented by major IS theories developed through quantitative studies such as the technology acceptance models. Perhaps more importantly, Q can be used to support the generation of high quality qualitative data and, or, strengthen the reliability of the interpretation of other forms of qualitative data, which is much needed in a field of studies where quantitative data remains mostly used, and lead to developing a new stream towards the development and study of technology.

KEY TERMS AND DEFINITIONS

Centroid: A factor extraction method which uses a specific form of communality estimation detailed in Brown (1980).

Concourse: The volume of possible assertions, in any format, on a given topic.

Conditions of Instruction: Designates the perspective that participants are asked to sort the Q-set from.

Flagged on a Factor: Signifies that a Q-sort is representative of this factor view based upon factor loadings (correlations between the sorters and the factors). Other outputs from Q are based only on sorts flagged on a single factor.

Hand Rotation: Sometimes referred to as judgmental rotation or theoretical rotation, this factor rotation is graphical rather than mathematical. This method allows researchers to rotate based on theoretical considerations rather than statistical ones.

PCA: A standard, mathematically unambiguous factor extraction procedure that can be found in standard textbooks on factor analysis.

P-Set: Those who proceed to the Q-sorting.

Q-Sample: The assertions chosen from the concourse to be submitted to participants for the q-sorting procedure.

Q-Sorting: The ranking of the assertions of the q-sample by participants (P-set) on the forced distribution matrix.

Varimax: Common orthogonal factor rotation method where the sum of the variances of the squared loadings (squared correlations between sorters and factors) is maximized.

Modernizing the Academic Library

University of Toledo, USA

INTRODUCTION

The digital age fundamentally changed how academic libraries operate. With the advent of electronic resources the job descriptions and duties of librarians expanded to include many of the same roles that IT professionals traditionally play. These roles include dealing with computers and software on a larger scale, as libraries attempt to stay current and relevant by adding computers to their building. How each library rises to meet these new challenges may be different, but there are a few things that remain consistent among them. Academic libraries in the modern age expect a different type of education and experience from their librarians. The administration expects them to deal with virtual materials and virtual resources, which requires different skills and expertise. These libraries have also adapted their mission statements and functions to reflect the change in their resources and personnel. Some of these changes have come slowly over the last two decades, while others have come fast, but they will not be the only changes that libraries will have to endure. Technology is continuing to change at a pace not seen before in history, and patrons are expecting the library to embrace it.

BACKGROUND

Most people would say that the digital age was born with the internet. However digital technologies are much older than that, dating back to computers built in the 1960s. Libraries at this time were using MARC records, which were digitized and are still in use today (Arms, 2012). Though digital databases and e-books were still far in the future, libraries began using this technology early on to improve the quality of the services that they offered their patrons. Libraries used technology to streamline services on both the back end and the front end, from the records that catalogers used to the way that patrons found materials in the library. Card catalogs became obsolete as computing power increased and those records were digitized. The libraries still had tons of physical materials for people to use in their research, but the digital catalog helped make it easier for people to find those materials.

In addition, telephones, not traditionally considered digital technology, helped the library answer questions without patrons having to be in the library. This was a marked change from previous interaction with patrons, because patrons no longer had to be in the library for them to ask questions. Much of the traditional reference interview relies on the body language of the patron and picking up on clues that they do not know they are giving off. Without the visual cues, librarians had to sharpen their ability to hone in on problems. This remote-access librarianship paved the way for other methods of contacting librarians, including e-mail, instant messenger, and chat services. Learning from what they had done with regards to telephone interactions, librarians adapted their reference interactions to serve their patron

DOI: 10.4018/978-1-7998-3479-3.ch121

populations through these methods. While this greatly increased the contact librarians had with patrons, it did decrease the number of people coming into the library, and that was only the start.

Technological advances led to even more changes for the library. When the world wide web and its contemporaries were established, they brought with them a new type of resource, the web page, which librarians had to learn how to vet for accuracy and timeliness (Arms, 2012). Though there were many contenders for what would become the internet, the World Wide Web persevered as the accepted software, albeit with many changes over time. These changes included the addition of colors and images, as well as behind-the-scenes information that could be registered within the properties of the web page, but there were still questions about the authenticity of the information being presented on many webpages. Because anyone could build a webpage, this led to misinformation and confusion among library patrons, a problem that still continues to this day. Academic libraries in their research capacity especially struggled with this problem as students began incorporating webpages into their research. Confusing the matter were many valid websites which held information that could not easily be accessed in other ways. Organizations and government departments began releasing content on the internet. Access became easy, but tracing the source became hard. Furthermore, studies at this time showed that, while students knew that the library had a webpage, and had access to the internet, those surveyed felt that the library and the internet were two separate things (D'Esposito, 1999, p. 458), leading to more concern that students were not receiving the best advice when it came to research materials. At the academic library, student-patrons also had to contend with professors who would not let them use online resources for fear of misinformation. This practice of barring that type of resource led to students not fully understanding how to vet sources on the World Wide Web for their own everyday use.

Databases were created to house materials that were both available in print and digitally. This led to database aggregators such as Ebscohost, JStor, and CSA. Libraries began allocating more and more of their budgets to these electronic resources. Database aggregators sold materials in bulk package, making the selection of large amounts of data easy. However, as libraries continued to sign agreements with these aggregators, they found that there was considerable overlap in the various collections, and that dropping parts of these agreements would increase the price of the packages, essentially giving libraries less information for more money (Zimmerman, 2010). However, libraries could not afford to drop out of the digital age entirely; students, now familiar with web searching, began expecting resources to be available to them online, without them ever having to step foot in a library. Digital technologies allowed the universities to offer classes online for the first time, swelling their enrollment numbers. However, academic libraries saw a decline in their patron numbers even as enrollment continued to grow. This juxtaposition of events required a response from the academic library.

ACADEMIC LIBRARIES RESPOND TO THE DIGITAL AGE

Early in the transition, academic libraries realized that they needed to change to continue to stay relevant. Some of these changes were simple, and included adding popular databases as they first began, or offering technology classes for their students who had missed out on those opportunities in high school. However, as public libraries and school libraries increased their technological advancements, academic libraries found themselves having to go ever farther to keep up with the demand of the digital age.

EDUCATION AND EXPERIENCE

When the digital age first began, the Master's in Library Science (MLS) was the accepted degree for librarianship, and had been since 1924 (Kennedy, et al, 2007). Library programs taught cataloging, reference instruction, and how to prepare research guides, among other things. Programs focused primarily on interaction with the patron. Even as technology progressed and these interactions were completed over the telephone or internet, the emphasis was still on patron interaction.

This concept began to shift with the introduction of the Master's in Information Science (MIS) and the Master's Library and Information Science (MLIS). Classes offered in these programs were more technology driven, and included metadata, database search systems, and social networking, the idea being that if librarians could understand the inner workings of the technology they were dealing with, they could better assist their patron population with that technology. In many programs, these classes were offered alongside the traditionally offered programs, and would often be listed as interchangeable in the course catalog. For example, at Indiana University, in the School of Informatics (formerly the School of Library and Information Science), Representation and Organization of Information, a class that focuses on theories of classification and metadata, is offered as an alternative to the traditional cataloging class. Students enrolled in the MLS program at IU also have the opportunity to take MIS classes as electives, while many others choose to earn a dual degree in both programs.

In the present age, now that libraries are more comfortable with technology, any of the three degrees discussed are appropriate for a position in an academic library. Many librarians still hold the traditional Master's in Library Science, including younger librarians, but the content of those degrees has shifted dramatically since the first library science degree was granted. About 78% of accredited programs have some technological requirement for all students, regardless of whether these students pursue library science or information science, with 11 programs (approximately 25%) requiring technology skills before admission (Scripps-Hoekstra, Carroll & Fotis, 2014). There is an overwhelming idea that even if a future librarian is not interested in technology, there are some basic skills they will need anyway to perform certain job functions. This has proven to be very helpful in preparing them for the changes in the materials and resources that the academic library uses.

Job-listings also changed with the increase in technological demands. Libraries began recruiting librarians that had experience with electronic resources, database management, and other technological experience. The number one change in job-listings is the advent of the new position, electronic resources manager, or electronic resources librarian. Whatever the permutation of the title, these jobs require intimate knowledge of virtual resources and virtual materials on a scale that had not been seen before. Equally important to the familiarity with the resources was a familiarity with vendor language and licensing agreements that differed from the traditional print publishers. Many of the licensing agreements contain carryover language from print resources (Masango, 2005), but these agreements can be complex and daunting.

VIRTUAL MATERIALS AND VIRTUAL RESOURCES

Virtual materials or electronic resources (e-resources) are now the backbone of many academic library collections. These e-resources include databases teeming with journal articles, conference papers, and book reviews, as well as e-books through various systems, and mp3s and streaming video for media collections. While the process of collecting these materials has grown increasingly complicated over the

last two decades, the importance of electronic resource managers (ERMs) and management software was relatively unknown for much of that time. While many smaller universities struggled to catch up by hiring ERMs in the last decade, other universities were pioneers in this field. Many of them designed their own software to catalog and maintain electronic collections at a time when few alternatives existed. These systems became forerunners of the electronic resource management systems that many libraries use today, but libraries are still finding that it is occasionally beneficial to create systems for themselves, because electronic resource management does not have a one-size-fits-all solution. Complicating matters is the fact that these solutions sometimes come late in the process. With virtual materials now taking up large amounts of the collection, both in terms of number of items and amount of money in the budget, special attention needs to be paid to the collection process.

Some materials, however, will not be digitized. There may be concerns with the process of digitizing them, or with the quality that will result from digitizing. Some digitization projects will be rejected due to copyright concerns. In these cases, there will have to be extra effort from the library to make sure their patrons are aware of what is available in the library, so that these materials are used. Still other academic libraries will have special collections, such as historical items or rare books that would not fit into the digitization model. These libraries are still a vital part of the library system at a university, and can be a great draw for researchers from around the globe. Marketing these physical materials alongside digital materials is vital to their continued existence. Otherwise, the materials will be deaccessioned from non-use.

The other option libraries have in the face of unused materials is to place them in archives. This is not always feasible for libraries due to budget constraints, but it is an option to consider when faced with unique materials. In that case, a dark archive would be the best solution. In addition to keeping these materials in your possession, it ensures that there will be an existing print copy of the material available to the world if the digitized version is lost. This is not only important for the institution holding the last remaining physical copy of an item, but for all libraries that would like to have continued access to items. It is, however, important to exhaust all efforts to find an extant digital copy of materials before embarking on a digitization project at the university level, because it can be costly, both in money and reputation, if mistakes are made.

There are special copyright rules associated with making copies and digitizing materials with the intent to archive them, and this can sometimes circumvent traditional copyright problems with regards to digitalization. Earnest discussion of this in law journals began with the Authors Guild, Inc. v. Google, Inc. case in 2013, in which Authors Guild, Inc. challenged Google, Inc.'s legal right to digitize copyrighted materials, on the grounds that Google, Inc. would be profiting from the digitization. The judge in the case ruled in Google, Inc.'s favor, citing that the in-depth indexing that was the direct result of digitization was substantively transformative, because it would help researchers be able to better find books (Authors Guild, Inc. v. Google, Inc., 2013). A similar case involving HathiTrust ended with the same results. This opens the door for more digitization projects in the future, though it does not negate the time and money required for such an endeavor.

Also of particular interest in libraries when it comes to electronic resources is the cost of materials. The cost of online databases has risen steadily in the last decade and will continue to do so unless suitable alternatives are found (Zimerman, 2010). While many libraries are ready to give in to the cost and adjust their subscriptions and purchases based on it, there are alternatives already available. One such alternative is the open access journal. The Directory of Open Access Journals lists over nine thousand journals in eighteen categories, each housing scores of smaller disciplines. Not only are these journals as good as their for-pay counterparts, but often they are preferred by researchers in their fields. In addition,

materials in open access journals can be supplemented by online repositories sponsored by universities. These repositories hold pre-prints of articles, as well as other materials, depending on the legal agreements the universities can make with the publisher. Many of them also house work that undergraduates and graduate students have done during their time at the university, making for a more well-rounded research body. Not only can students see what is being pursued by researchers in their field, but they can also see what work their fellow students have been doing, encouraging collaborative work within disciplines and without.

MISSION STATEMENTS AND LIBRARY FUNCTIONS

The rise of digital material required a response not only from the librarians out in the field doing work with patrons and acquiring and cataloging materials in technical services, but also from the administration governing these librarians. It has long been accepted that universities would have mission statements at both the university level and at the department level, which would be organized in tandem so that the university was working toward one united goal. As their roles on the university campus changed, academic libraries needed coherent mission statements that encompassed all the work that they were doing, not just their role as repositories for the physical book. Mission statements began including language about the technology, itself. For example, in Western Kentucky University's mission statement, the fourth tenant is, "Maximize digital technologies and develop networked resources that enhance learning (WKU Library Advisory Council, 2013)." These new mission statements do not just deal with library technology as a burden that has to be dealt with, but as a tool for improving library resources and service. Activities that go along with these mission statements include building information commons, where students can gather and partake of information through a variety of means, including print and digital. They often also have televisions tuned to news headlines and group study areas for students to work collaboratively.

This reflects the changing library functions. Libraries are now a collaborative area filled with students working in groups. In a way, this is just the library catching up to what has been done in the classroom for decades. Group projects had often been assigned to students in years past, and these projects were often carried out in the computer lab, or shut away somewhere in a group study room. However, libraries can, with technology, now embrace these group projects and make it easier for students to work. Now the library is a place where that work can be done easily, with access to all of the materials the group would need. Though there are librarians on duty to help students with questions, the stereotype of the shushing librarian has been shattered. This was a change necessitated by falling patron counts; as students began accessing materials on-line, libraries had to find other reasons for students to come into the library. One of the library's best resources is the space that they provide for students to work, and this was a resource that was underused because the space had not adapted to fit changing work demands.

Changes in how librarians view resources, and what constitutes a resource, have also facilitated new growth in the library. Both academic and public libraries have makers' spaces in which patrons can experience new technology that they might not be able to access or afford outside of the library setting. The tools that constitute makers' spaces can be either digital or physical in nature. Examples include video production software, laser cutters, and builder kits. Depending on the patron population, any or all of these might be available at the library, and are usually tailored to meet the demands of certain majors. Though maintenance and materials can be costly, these types of tools have become more resources for the library to offer.

TECHNOLOGICAL PARTNERSHIPS

In a quest to stay relevant and form connections within the campus community, academic libraries have forged technological partnerships with other departments on campus. Some of these partnerships are necessary; today's libraries have a great deal of technology, including computers, printers, televisions, etc., and they often need their own dedicated IT staff to troubleshoot these devices. Furthermore, because the library is a place of study and work, many students bring their own technology into the library. To serve their patrons better, some library IT personnel also answer questions from patrons about devices and software, solving problems much quicker than librarians typically would.

Not all library-technology partnerships are strictly by necessity, however. Some partnerships are forged because libraries have space, where stacks once stood. When materials are digitized and their physical volumes discarded or archived, libraries can open up the space to other academic departments. Other partnerships are created because the library has a mission to embrace all forms of learning and information gathering. These partnerships can take a variety of forms, including makerspaces, virtual reality labs, and listening libraries. The aforementioned makerspaces increasingly popular in libraries even without official partnerships, though they are sometimes sponsored by an associated academic departments to offset costs.

Regardless of their exact nature, these partnerships are mutually beneficial, because they provide a space for the programs involved and in turn bring more people into a library. In an era where statistics are important evidence of worth, the more people counted going through the library doors, the better. Furthermore, these and other types of partnerships foster goodwill in the campus community and provide a moderate amount of publicity for the library (Wainwright & Davidson, 2017). Some innovations, such as learning and teaching labs, get even more out of the partnership, because they can take advantage of the materials the library already provides.

SOCIAL MEDIA

As a digital presence becomes essential for the continued stability of all companies and institutions, academic libraries have also begun embracing social media, whether as an entity on their own or as part of the larger college or university. Social media has many definitions in the literature, but can be broadly defined as, "the means of interactions among people in which they create, share and exchange information and ideas in virtual online communities and networks (Fang, et. al., 2014, p.336)." Most universities have some policy on who can use social media networks on behalf of the university, and the library's ability to control their own online presence would be affected by those policies.

However, an online presence for marketing purposes is not the only reason libraries should embrace social media. Social media can be an effective tool in the classroom for information literacy. Librarians who teach information literacy classes have embraced Twitter, Facebook, blogs, and more in an effort to foster communication between students and between students and their instructors. Even one-shot library classes can use social media for quick communications during the course of the class, through the use of hashtags on Twitter, or polls on interactive websites, or discussion boards on the various learning management systems.

There is also a third reason for academic libraries to embrace social media. Social media networks have become powerful tools for information exchange in a brief amount of time. Because of this, the general public is less educated about how to vet these sources. Academic libraries should take it upon

themselves to see social media as an information literacy topic, to be taught in classrooms and discussed in presentations and publications by the library. Through these methods, students will become better acquainted with this use of social media networks and the potential problems of taking information at face value.

FURTHER RESEARCH DIRECTIONS

The challenges that libraries face today could potentially sound the death knell for smaller academic libraries. Students no longer believe that libraries have the monopoly on research materials, and they are right. Google scholar has become a serious challenge to libraries despite a pushback against it from librarians, because it is attached to a name that nearly everyone knows – Google. Most students, especially undergraduates, can find the materials they need for their class projects from the comfort of their own home computer. Part of the way to combat this problem is to embrace the supposed enemy. Google scholar can be a very effective tool when used properly, and if a student has the system set up correctly, they can even use Google Scholars' search features to search their own libraries. This search feature has been immensely popular with students, but other databases are still important to the research process and may have search interfaces more suited to the search topic at hand. Libraries have to become creative when trying to draw in students to their libraries and to use their resources.

This can be accomplished through a strong connection to the faculty. Students see faculty every day and are more likely to take their advice when it comes to research and their grades. Set up library instruction sessions for classes, and be sure the students know what's in it for them when they attend. Explain to them the difference between searching in Google and searching in a database, and how the latter can actually be easier and quicker to do once they know how to do it. Running through search questions in the various databases can demonstrate to them the different types of results that they can get. Furthermore, it will show them that it can be difficult to retrieve materials when one is not logged in to a university database.

Other suggestions for making a library more inviting and adaptable to the changing digital world include creating collaborative learning spaces that integrate technology with the learning experience, adding outlets and power stations to facilitate the use of laptops, tablets, and other portable electronic devices. Information commons like the one discussed here are an excellent way to facilitate this change and are very popular subjects for funding and grants at this time. They provide a seamless entrance for the library into the world of technology and provide a valuable resource for the students. Furthermore, if a campus has a technology center that is not part of the university library system, an information commons can artfully redirect this traffic back to the library. This way, students will have academic librarians on hand to answer questions when or if they arise, making the research process easier and encouraging them to continue their studies.

The last advice for the academic library in the digital age is to consider changing how success is measured. A library whose success is measured by the number of people walking through their physical gates and using their brick-and-mortar building is going to be disappointed by the numbers that they see. Universities are more flexible with their class models, offering more classes online, and therefore many people may never step foot on the university campus, much less in the university library. Rather than letting these students languish, struggling on their own to accomplish research while their counterparts on campus have all the help they could want, university libraries should be working with advisors and classes to make sure that they are also reaching out to these students. There are a variety of ways that

this can be done, including web tutorials, research guides, and videotaped presentations on library resources that can be embedded in the software that the university uses for their online classes. The tools to reach these students are available, and helping them should count in statistics in a meaningful way. All ways that the university resources are accessed should be given equal weight, because the university is still providing a valuable service, whether librarians are conversing with patrons through email, on the telephone, or in face-to-face interactions. Even keeping track of patrons accessing virtual resources through OpenURL can be an eye-opener to the way that the academic library is helping their students (Wright, 2014).

CONCLUSION

Today's library exists in a very different world. Much of the library's content is digital, and can be accessed online. Some materials, however, cannot be digitized at this time because of technical or copyright concerns. Identifying these materials and integrating them into the curriculum is important for their continued value and to increase patron counts in libraries. Equally important to libraries is the constant innovation of new resources and outreach methods to serve the patron population. Changing how they measure success will also help libraries justify and evaluate programs, because it will highlight the way that their services have changed over the years. For the most part, libraries are already keeping track of statistics in many and varied ways, and acknowledging that these changes exist. However, they are not doing enough to put more emphasis on those reference interactions and that resource usage, when they should be. By embracing the digital age, libraries will survive and thrive far into the future.

KEY TERMS AND DEFINITIONS

Academic Libraries: Libraries affiliated with universities or colleges.

Digital Age: From about 1980 on, coincidence with the advent of the world wide web.

Digitization: Scanning or otherwise manipulating print materials into an electronic format.

Electronic Resources: Library materials available in an electronic format.

Mission Statement: Unified theory, plan, or goal of an organization or subsection of the organization.

Social Media: Websites and applications allowing users to network and share information.

Prospects and Challenges of Web 3.0 Technologies Application in the Provision of Library Services

INTRODUCTION

Information and Communication Technologies (ICTs) have continued to redefine and transform the way and manner library and information services are conceived, perceived, offered and used. While it was a subject of debate that the attendant effects of the emergence of the internet and web technologies would mean the devaluation of library and information services and perhaps the demise of the profession, events shaping the information sector have proved that like technology, the field of librarianship is adaptive and evolving. Definitions, concepts, theories and practices once considered “core” or “modern” or “of international best practice” have become obsolete, inadequate and unacceptable due the various paradigms swings that have greeted the profession overtime (Izuagbe, 2017). This further strengthens the argument that the library profession is moving from “building collections” and owning them forever to “renting access” and having ‘connections’ (Hielmcronne, Maiello, Bainton & Bonnet, 2012).

The wide acceptance and adoption of technological innovations in the 21st century libraries is placing emphasis on the application of web technologies due to speed and accuracy (Govanakoppa & Kumara, 2014). Accordingly, libraries that are currently blazing the digital trail are striving towards web services. A web service is a modern application of computing technology aimed at the facilitation of exchange of communication between or among interconnected computers that is internet-based (Amrohi, Garg & Chauhan, 2015). While this service best describe the principles of web 1.0 and 2.0 respectively, it omits

DOI: 10.4018/978-1-7998-3479-3.ch122

the unification of these technologies and users for an all-inclusive problem-solving and knowledge-creation efforts which web 3.0 entails. It is on this note the article sets out to examine the prospects and challenges of web 3.0 application in the provision of libraries services. Specifically, the paper gives insights into the principles and features of the technology, explore areas of applicability relative to library services, highlight the prospects of the technology as well as its challenges within the precincts of library services.

BACKGROUND

The sophistication and rapid dynamism that characterize the ICT have necessitated the need to leverage on latest discoveries in searching, tracking, accessing, disseminating and sharing from the global information network as well as connecting with people and communities for mutual benefits. The World Wide Web has made possible the instant linkage of information resources and people on the cyberspace. It began with the advent of web 1.0. This is a system of interlinked, hypertext documents through the internet. It was a read only platform having focus on one way communication. Users were allowed to search for information and read same with little interactivity and contribution to content. It was aimed at providing online presence for requisite information through websites (Kadyan & Singroha, 2014).

The improvement over this phase resulted in the emergence of web 2.0 in 2004. This version foisted a truly virtual global community where users could share, interact, and collaborate with others on the social media platform. This gave birth to networking sites such as Facebook, YouTube, Blogs, Wikis, Flickr, Twitter and WhatsApp. As a result, the technology has been described as a veritable tool for internet marketing of product and services (Ekwueme & Ilo, 2019). Following in the rapidity of the heightened developments in the programming world, John Markoff mooted on the idea of Web 3.0 in 2006 (Morris, 2011). A web 3.0 is a centric delivery pattern in which relevant data are provided to end users on different platforms and devices in a most usable manner. It has the ability to aggregate information from multiple sources and establishing semantic relationship between all available contents to ensure seamless accessibility, searchability, availability, and usability. It allows interoperability with other devices such as tablets, smartphones, and desktop computers, iPads. It also supports offline use or consumption of downloaded data, therefore making it possible for the exploitation of information in a low bandwidth conditions.

This is made possible by the use of web cookie and client side storage facility present on client device. Kadyan and Singroha (2014) summarized the features of web 3.0 as constituting: intelligence, interoperability, personalization, and virtualization. Web 4.0 also known as symbiotic web aims at interaction between human and machines. It is an open, linked, and intelligent web. It is the basis for the Internet Of Things where smart appliances connected to the internet will be able to perform tasks without human involvement based on the use of radio frequency identification tags (RFID) (Kang & Yong, 2007; Kodyan & Singroh, 2014; Letts, 2018)

The need for the application of web 3.0 technologies in the provision of library services is premised on the ever increasing effect of emerging technologies on education and the growing demand on the capacity of librarians as well as the need for higher strategies in meeting the sophisticated expectations of the ICT-savvy clientele of the 21st century. The present library patrons are desirous of federated library databases that collocate relevant contents from multifaceted sources and facilitate interactive information exchange, scalability, and collaboration on the web. The information seeking behaviour of an average library patron has been revolutionalized by the limitless scope of the Internet and the World Wide Web

in information retrieval. The usual first point of call for information seekers in the twenty-first century is the Internet (Rao & Babu, 2001; Coffman, 2012; Purdine, 2012 & Nkiko, 2014).

FOCUS OF THE ARTICLE

Library 3.0: Application of Web 3.0 in the Provision of Library Services

The usefulness of web 3.0 technologies has become a critical factor that would drive the applications of these emerging technologies to many areas of life. There is a growing interest in the use of these technologies to provide library services. Library 3.0 represents a transformation from Library 2.0 to Library 3.0 with the application of Web 1.0 and Web 2.0 elements. In Library 3.0, library professionals are expected to provide services to library users based on web 3.0 technologies.

Library 3.0 refers to libraries using emerging technologies to facilitate the sharing of use-generated content as well as collaboration between libraries and their clientele. Semantic webs include cloud computing, mobile devices and established tools like federated search systems to facilitate the development and sharing of use-generated content, collaboration between librarians and users, and to promote and make library collections widely accessible, searchable and usable (Belling, Rhodes, Smith, Thomson, & Thorn, 2011). Library 3.0 can make library collections readily available to users irrespective of their physical location. Some of the key elements of Library 3.0 are speed, accuracy, precision and systematic organization, (Chauhan, 2009).

Whereas the origin of the concept of Library 3.0 is controversial, its benefits are inexhaustible. Firstly, it seeks to make all web contents seamlessly accessible, searchable, available and usable (Chauhan, 2009). By so doing, the right information will definitely get to the right user at the right time. Secondly, in the Library 3.0 environment, library users can work together with the Librarians as co-creator of contents and services. Further, it enables library users to make annotations and carefully compare books and other information sources from a variety of useful perspectives. Thirdly, Library 3.0 It promotes dual interaction between computers, OPACs and libraries (Nesta & Mi, 2011).

Fourthly, Library 3.0 is likely to create a network of libraries with distributed collections, multiple interfaces as well as traditional and non-traditional forms of scholarly communication (Libner, 2003). This is premised on the fact that institutions with Library 3.0 will hold large collections in all forms and formats including web pages which will all be accessible anywhere. Finally, Library 3.0 seeks to provide full-text information with a fully integrated deep search environment and provide ways library services can be offered to required services and collections that will exceed patrons' expectations (Bhat-tacharya, 2016).

Principles of Library 3.0

Library 3.0 has some basic principles. Though Library 3.0 principles were scarcely treated in library literature, Saw and Todd (2007) were able to propose five basic principles of Library 3.0. First, the library is intelligent. This means that Library 3.0 uses artificial intelligence (AI) systems to offer intelligent services to library users. As an aspect of AI, intelligent library within the precinct of higher education facilitates personalized leaning, learning analytics and intelligent tutors (Cox, Pinfield & Rutter, 2018). The authors noted further that intelligent library system builds and develops collections and services for

an intelligent agent rather than a human audience. With the aid of intelligent library systems, it is easier to make libraries, not only interactive, but more user-friendly (Dent, 2007).

Second, the library is organized. This means that Library 3.0 model is designed to describe or organize web resources in a manner that users can access them easily. It emphasizes the library coming to the patrons in a proactive and interactive manner, leading them rather than following, innovate, rather than copying (Nesta & Mi, 2011). Third, principle of web 3.0 the library is a federated network of information pathways. Library 3.0 is designed to promote federated searching from a federated list of web resources facilitated by cloud computing systems (Belling et al, 2011). Fourth, the library is apomediated. This explains users sidelining conventional information gatekeepers through the use of technological platforms (Eysenbach, 2008). Whereas social media is helpful in this regard (O'connor, 2010), librarians can apomediate by either providing clues necessary for helping users locate the right information (Sapp & Van Epps, 2006). Finally, the library is MyLibrary. Library 3.0 is designed to provide personalized library services to the users. To achieve this, librarians and users employ Library 3.0 tools to create personal and professional profiles that help to provide user- centred library services, or help to fit library services into the lives of the users (Cohen, Ferreira, Horne, Kibbee, Mistlebauer & Adam, 2010).

Features of Library 3.0

Library 3.0 has some important features. One of the features of Library 3.0 is Web OPAC. This is a library catalogue on the Web or internet. It has a Uniform Resource Locator (URL) which users can connect to and search the required or needed information. Web OPAC has come to replace the card catalogue and has searchable functions for borrowing and automatic reservation. Library users can also request for any kind of information such as contact details, email addresses, new arrivals as well as borrowing rights and privileges. Another feature of library 3.0 is that it makes use of ontologies. In the library context, ontologies are used to provide annotation to web contents. Ontologies are used to show how information is organized. Finally, Library 3.0 enables the creation of personal contents known as ubiquitous contents which can be stored on the web.

Library 3.0 and Virtual Reference Services

Librarians are gradually utilizing the potentials of technological innovations to serve users in remote locations. Bhattacharya (2016) citing Linda Berube (2003) defines virtual reference as a network of expertise, intermediation and resources placed at the disposal of users who need answers in an online environment. This author further state that virtual reference ranges from personal or telephone assistance given to users to developing contents that can be accessed via smart phones and other mobile devices. The author concludes with the following objectives of virtual reference in the Library 3.0 era:

- i. To provide individual assistance and instruction.
- ii. To provide and maintain an appropriate collection of reference resources, both print and electronic
- iii. To assist users with locating the best sources of information.
- iv. To help in marketing reference resources and services
- v. To help in referral process, forward the enquiry or provide the users with live links to authoritative websites.
- vi. To educate users concerning resources and research techniques in order to help them to become information literate.

Reference service based on Web 3.0 environment means new roles for librarians. Some authors have agreed that librarians would function in this new environment as virtual librarians (Alenezi, 2012; Pinto & Manso, 2012). In specific terms, librarians should consider using the library homepage as a reference tool or as a tool for the provision of online reference interview. Furthermore, the authors suggests that librarians should begin to use desktop videoconferencing to provide reference service.

Semantic Web and Library Services

In this digital age, the first source of information for students, researchers, scholars and faculty members is the World Wide Web (WWW). The problem with the www is that its documents or information sources are usually in the form of Uniform Resource Identifiers (URI) and the information in them is not machine readable. However, the semantic web has emerged to address this issue. The semantic web provides a common framework for sharing of data and information in an organization such as a university library. This web consists of both structured and unstructured documents. The semantic web helps to convert the unstructured web documents into web data for global knowledge exchange.

The semantic web is an extension of the current web in which information is given well-defined meaning, enabling computers and the people to work in cooperation (Berners-Lee, 1999). From this definition, the semantic web accomplishes two things; providing machine readable description of web documents and giving meaning to the content on the web documents. When these two things are accomplished, all the machines linked to the semantic web will be able to gather and analyze information automatically in a manner similar to that of human beings. The resultant effect of this is that more relevant and meaningful information will be retrieved. These technologies include web ontology language, Notation 3 (N3), Resource Description Framework (RDF), SPARQL, which is a RDF query language, Turtle (RDF Triple language) and RDF schema (RDFs). Apart from these technologies and standards, semantic web can be realized through artificial intelligence. When this happens, the computer systems will be able to make decisions like a human expert and not by relying on computer algorithms and procedures for this purpose.

In the library, semantic web can be used to develop library portals. The implementation of library portals with semantic web services will definitely help to fulfill the vision of the library. By this implementation, the large collections of the library are annotated semantically by using various software technologies, or this implementation involves annotating the web content information of library resources and providing a semantic description of this content so that it can be machine readable. Formal ontologies or ontology schema are used to provide more flexibility in the semantic description of this web content information. The necessary condition for the functionality of library portal with semantic web services is that the portal's user interface must help the user to search, retrieve and access information from multiple sources.

Furthermore, other library operations that can be made available to semantic web applications are library catalogues, cataloguing of digital resources, collection development policies and reference services. The library catalogue has structured content which makes it have the characteristics of semantic web. For this purpose, the semantic web focuses on the framework for describing information sources and making them available for public use. This, of course, will lead to the development of semantic catalogue that would have ontologies, authority verification and MARC based schema. The semantic web application in collection development begins with ensuring that the collections developed have the characteristics of semantic web.

IFLA guidelines for information services and other resources on digital reference (Lipow, 2005) can provide an acceptable framework for the implementation of semantic web reference service plans.

Furthermore, the semantic web resources are expected to be used by students, faculty members and researchers. Just the same way circulation policy protect library holdings and promote their use, a semantic web resources use policy should be in place for the same reason. That is, this policy should promote web resources use and protect these resources as well. The policy should, as a matter of necessity, provide users with access procedures, a unique identification number and knowledge of their borrowing privileges.

It is important to point out here that the most commonly used semantic web software technology is the Resources Description Framework (RDF). The reason is that it has several applications. Some of them are Friend of a Friend (FOAF), which is used to describe personal information and describe people including the links between them; Simple Knowledge Organization System (SKOS), used to improve recall and precision ratio and to provide searching options or features for users; DBpedia that provides interface that users can exploit to query relationships and properties associated with resources and to provide links to related datasets; and Resource Description Framework for attributes (RDFa) used to annotate web pages.

Cloud Computing and Library Services

This is one of the Library 3.0 applications that are increasing gradually in popularity on daily basis. Simply put, cloud computing refers to the use of internet and central servers that are remotely located to maintain data and other applications as opposed to maintaining data using personal computers or individual mainframe computers (Kwanya et al., 2012). The advantages of cloud computing for library include lower-cost computers for users, better performance, less IT infrastructure costs, less maintenance costs, unlimited storage capacity and anywhere access to documents (Stinivas & Chary, 2017). Many companies are now providing cloud based digital library services. One of them is Duraspace that has two software now in use, namely: “Dspace” and “Fedora commons”. Of the two, Dspace is widely used by libraries to build repositories aimed at providing access to research output and scholarly content. Bhattacharya (2016) summarized the applications of cloud computing in libraries thus:

- i. OCLC is one of the best instances for making use of cloud computing for sharing libraries’ data. Its world cat is the most popular online union catalogue for searching library data.
- ii. To access any files on the internet, cloud computing presents a number of services such as flicker, Drop box, Juggle Disk, Google Doc, Sky Drive and so on. These services virtually share the files anywhere and anytime without any special software and hardware.
- iii. Cloud computing technology offers great opportunities for libraries to build networks among the library and information service professionals as well as other interested people including information seekers by using social networking tools like “Twitter”, “Facebook”, “Instagram” which play a key role in building community power.
- iv. For automation purpose, ‘Polaris’, ‘Ex-libris’ provide variant cloud based services such as acquisitions, cataloguing, process system, digital contents and also support various standards such as MARC 21, XML, Z 39.50.

Finally, examples of cloud service providers for libraries include OCLC, Ex-Libris, Polaris, Scrib, Discovery service, Google Doc and Google Scholar.

Federated Search and Library Services

Libraries introduced portals so as to be able to bring large amount of information together. A portal can be defined as a gateway or a point for information searching on the web. It is seen as the point where students, researchers and scholars or simply users can start to search for relevant and important information on the web. There are indeed different types of portals such as institutional portals, subject portals and federated search tools (Kumar, Sanaman & Rai, 2008). According to these authors, federated search tools are used for integrated access to the resources that the library pays for and they also allow cross-searching of these resources. It is important to note that authentication is often required. Further, the federated search tools work by using Z39.50 protocol for communication between computers. The Z39.50 helps users to extend information search beyond the online virtual catalogues to searching electronic databases that are remotely located but are authenticated at the point of access.

At its basic level, federated search is simply simultaneous searching of multiple online databases or information sources. This means that through one search query users view search results from multiple information sources in a single integrated list. Federated search enables users to search many OPACs, websites, and subscription and citation databases at the same time. It is pertinent to note that federated searching is an important part of an information portal because it provides a single interface to diverse or multiple information sources. For example, once a student enters his or her search query in the search box of the information portal, the query or search string is sent to each information source in the information portal or federated search list. Based on the search query, the individual information sources will send a list of results to the information portal. At this point, the student can view what has been retrieved from each information source in a single integrated list of search results.

Federated searching is somewhat different from traditional search engines such as Google. By using Google, only information sources that have been indexed by the search engine's crawler technology can be searched and retrieved or accessed. The same applies to other traditional internet search engines which means that documents in databases that are not open to these search engines can neither be searched nor retrieved or accessed due to the limitations in crawler technology. Federated search helps to solve this problem by making deep or invisible web documents searchable without having to search each database (Chen, 2006).

In the library environment, the appropriate federated search technology to be used is Z39.50, whereas Liberty is complete web based library automation software for federated searching. Liberty offers library managers the option to include library catalogue in the federated search list and to select other databases to be included in the list. This actually makes Liberty to be customizable. On the other hand, Z39.50 is an open network standard which facilitates communication between systems that run on different hardware, with the use of different software. This makes it possible for a searcher to use the library portal's user interface to search both the local catalogue as well as any database that supports Z39.50. When a federated search is implemented in a library, it becomes a unique library service.

Mobile Library Services Within The Context of Web 3.0

The new information environment is changing rapidly and libraries are seriously under expectation to provide innovative services to meet the ever expanding needs of users. To this end, innovations in mobile library services are needed or required to meet users' needs. According to Kumar (2013), these mobile library services are an extension of digital library in the mobile communication network. Digital library and mobile communication are necessary conditions for mobile library services. Mobile technologies

such as Blackberry, iPod, Smart phones, Cell phones, Tablets, MP3 players and Personal Digital Assistants (Kumar, 2013; Saxena & Yadav, 2013) are being deployed by libraries to offer innovative and user-focused services not limited to the following:

- i. Voice service: Libraries are providing voice services with the support of mobile phones. The simplest of this service is welcoming library user into the library.
- ii. Short messaging service or text messaging: Short messages can be sent to library users through mobile phones. The messages may take the form of reminders to return library material, information on outstanding loans, library events and new resources on the library website or portal.
- iii. Multimedia messaging service (MMS): Libraries can use MMS or mobile phones to share photos, videos and radio.
- iv. Question answering service: Library users who have questions on how to use the library for a specific purpose can contact the librarians for help through mobile devices.
- v. Mobile OPAC: The Online Public Access Catalogue (OPAC) serves as a link between the user and the library collection. New mobile based OPACs are being developed to help users have access to library collection through mobile phone devices irrespective of the location of the users.
- vi. Data service: Mobile phones can now be used for web browsing and to send email to library users.

Besides, libraries can generally use mobile devices to provide practical information and bibliographical information (Ally, 2008). The practical information to be provided include address, email ids, phone numbers of the library, opening hours, rules and regulations of the library, and information regarding staff. Also, mobile library sites can provide links to quick information such as covers, news, mobile catalogue, workshops/programs and contact information. The bibliographical information is not location dependent since online or electronic bibliographical metadata can be saved or stored remotely in a server or in the cloud, and this could be accessed anytime. Users can use their mobile devices to make inquiries about books, catalogues and so on.

Prospects of Web 3.0 Applications

Libraries are growing organism which responds to evolving external environmental stimuli. The volatility of the virtual world as dictated by various phases of web technologies remains the major driver of changes in modern libraries. This is usually associated with the need to help library patrons navigate and ferret out specific information from the maze of diverse and plethora of available contents in the era of information explosion. It is in the light of the foregoing that Web 3.0 technologies are embraced in the libraries as most required development.

The semantic digital library would transcend collection of electronic books and journals to providing automatic interconnection among other fragments of hyper books from variegated sources. This enhances precision in the online retrieval system thus, leading to availability of enriched contents to users. The Web 3.0 platform makes possible the concept of virtual reality which leverages on the sophistication of smart phones and other mobile devices. This provides emergence of novel information services by merely scanning the Quick Response Codes (QR) as an interjection between the objects in the real world and the Web. Library patrons can save the author, title, and shelf number of desired library materials in their mobile phones for later retrieval and reuse purposes.

Virtual Reference Services have also become a distinguishing feature of semantic web libraries. Readable and audio contents are now transferrable to group or individual patrons to meet their informa-

tion needs as well as providing necessary digital analytics based on an artificial intelligence embedded interfaces, thereby enriching the information literacy skills of library users. The semantic web or Web 3.0 will also provide a departure from the current system of over dependence on bandwidth size for the functioning of the electronic libraries. This is because Internet is no longer restricted to computers but accessible on mobile devices. It is indeed a precursor to crystallization of libraries in the cyberspace.

The availability of WEBPACs (Web Public Access Catalogues) would be a distinguishing feature of modern libraries which is one of the components of Library 3.0. It is about remote login to the library catalogue on the cyberspace through a Uniform Resource Locator (URL). This makes the Library accessible anywhere and at a time resulting in a truly borderless library services. One of the greatest needs of the library users is the desire to collocate information from multiple online databases with divergent login details and display formats. Federated search mechanism powered by web 3.0 allows for search results to be aggregated in a single platform just like Google search. This functionality could be integrated into library management software application for effectiveness.

Web 3.0 would expand the propensity and increase adoption of cloud computing in libraries. It is becoming fashionable for academic libraries to build institutional repositories for the preservation and global visibility of their publications and research output using Dspace and E-print which are products of cloud computing. Collaborations and sharing are now mediated by online union catalogues. Libraries in Africa and other continents engage in copy cataloguing by merely login to Library of Congress and OCLC online catalogues to retrieve bibliographic records of library materials and depositing same into their server with little or no modifications.

The artificial intelligence dimension of web 3.0 makes possible the use of robots in library services. This degree of embedded system automation introduces a pick and place robot manipulator to pick books and other materials and place them in an orderly manner in pre-designated location (Lande et al, 2015). The Robots through Radio Frequency Identification (RFID) tags are capable of tracking misplaced items on the stacks, thus enhancing shelf order and speed of the retrieval system in the Library. Also through geo tagging of digital contents, library patrons with smartphones and other mobile devices having GPS (Global Positioning System) functionalities can ferret minutest information from definite locations.

Lu, Ming and Farshed (2003) summarized the prospects of web 3.0 applications within the Library context thus;

1. Library 3.0 helps librarians to provide web services to users. Web services are often regarded as one of the resources in the semantic web. Specific activities can be performed by information professionals while providing web services to users. One of such activities has to do with providing details of user interface agents that assist users on how to browse the World Wide Web. This is known as automatic web-service discovery. The next activity also involves making available to users some software agents that will interact with the web-service on specific requests or inquiries from users.

The reason for this is that multiple interactions are required between users and web services. The library users only need to tell the agent to go to amazon.com to buy a book titled 'Introductory to Economics' with not more than a certain amount of money. This is called automatic web-service invocation. Another activity by librarians involves guiding library users on how to automatically select and compose a new web-service to achieve a new objective. This process is called automatic web-service composition and interoperation. Finally, library users can be trained on how to tract and query the status of the execution of each service or request automatically. This is referred to as automatic web-service execution monitoring.

2. Information professionals are expected to utilize the potentials of the semantic web to serve the users better. The semantic web uses ontologies to describe various web resources in a structured, logical and semantic way which makes it very easy for users to have access to them. Ontologies help to bring diverse knowledge bases together and ensure that a collection of web services are equally described semantically. These knowledge bases and collections of web services are regarded as semantic web resources that provide a rewarding web experience to library users.
3. With the advent of semantic web, resources on the web are represented in ontologies. This means that ontologies can help to build semantics-based search engines. When search engines are guided by ontologies, recall and precision of search result will be increased, thus helping library users to have ease of access to various web resources. The reason is that ontologies keep content, structure and representation of an entity or knowledge agent apart. For instance, if something on “chairs” is needed or searched, two separate search results are likely to pop up. With the guidance of furniture ontology on one hand, furniture chairs will be obtained and with the guidance of person ontology on the other hand, persons who chair organizations are likely to pop up.
4. Library 3.0 promotes semantics-based retrieval of multimedia data repositories. This is important because libraries are directly having issues with the traditional content-based multimedia data retrieval due to their low features such as colour, texture and shape (Smeulders, Worring, Santini, Gupta & Jain, 2000). This problem seems to be compounded with the emergence of multi-media digital contents.

The application of web 3.0 technologies in the provision of library services provides phenomenal innovation and transformation in the entrenchment of efficiency and effectiveness in knowledge management. It gives an impressive picture and foretaste of the library of the future.

Challenges of Web 3.0 Applications

New technologies representing new opportunities often impose new challenges. These challenges differ from one web application to another. This section tries to present in a nutshell some of these challenges in developing a semantic web, managing the clouds for library services, deploying mobile communication technologies within the Web 3.0 environment and federated search systems.

Developing semantic web resources is time consuming. The reason is that the semantic web involves the creation of two formats for human and machine components. Another challenge is that the amount of information on the web today which creates concepts that are vague, contradictory and deceptive or generally imprecise and confusing. There are also other issues, such as cost, increased workload, censorship, privacy, duplications and so on, that are likely to hinder implementation of semantic web services in the library. Security and privacy are the biggest concerns with clouds management. Others issues, according to Stinivas and Chary (2017), are: the service providers can limit certain projects to certain clouds, usage tracking of multiple clouds is tedious and service providers often hide deployment details from users through virtualization.

Access authority is required for mobile communication technologies; otherwise there could be a security breach. Also, the user interfaces are varied and lack standards, which means that choice of user interface is a serious issue (Kumar, 2013).

Some databases cannot work with federated search at all, especially those ones that do not use web browser such as SciFinder scholar (Kumar et al., 2008). These authors further state that any database

that requires a login does not work with the federated search. Secondly, some databases can work with one federated search but cannot work with the other. Thirdly, the number of concurrent users for some databases is limited. This means that if someone logs into the federated search, no other person can use those databases. Fourthly, many libraries have databases on a pay-per-search basis and would not want the databases to be included in the federated search for budgetary or economic reasons. Federated search systems are basically software and as such are implemented as a service which takes quite a number of resources. Finally, in federated searching, only basic Boolean commands are used.

In their contribution, Lu et al (2003) have identified and summarized these challenges as;

1. Ontologies play critical role in organizing semantic web resources, but it is challenging to develop ontology library systems.
2. Semantic web languages have become an integral part of the semantic web as they constitute greatly what is commonly referred to as semantic web resources. The challenge is that many of these semantic web languages like RDF, RDFS do not have formal semantics. This makes it difficult but not impossible to develop semantic web. This implies that the semantics of RDF and RDFS need to be resolved by either defining formal semantics for them, or by ensuring that the problems of these languages are mainly a matter of semantics.
3. With the semantic web, anybody can say anything to anybody. Today, people can make statements that conflict. Because of this, it becomes necessary that attention is given to original statement from a known source (Proof) in order to ensure that the source is trustworthy (Trust). The challenge here is that the concept of proof and trust is yet to be formalized and a theory that integrates them into the analytics of semantic web resources is also yet to be developed.

In their summary of the challenges of emerging technology adoption in libraries, Saw and Todd (2007) identified workforce skills shortage and the librarians' stereotype and personality type as some of the barriers to the full and successful adoption of Library 3.0. They further added that libraries tend to dwell so much on the experience of the past or rather on successes made in the past, which affects the adoption of emerging technologies such as Library 3.0 model. Finally, the authors are of the opinion that institutionalization, innovation, imagination, ideation and inspiration are real issues that can fast-track the full realization of Library 3.0 model.

FUTURE RESEARCH DIRECTIONS

Effort has been made in this chapter to extensively discuss the practicability and challenges of web 3.0 technologies in the library environment. As a result, adequate light has been shed on the potentiality of the technologies towards enhanced library services. However, the chapter is not in any way claiming exhaustivity, as the subject of the research could be extend further for wider applicability. For example, taking cues from literature to examine the prospects and challenges of web 3.0 technologies relative to library services (as this chapter has done) does not have empirical basis for making definitive conclusions. Therefore, future research should focus on highlighting the benefits and possible challenges of the application of web technologies from an empirical context. Similarly, examining the phenomenon within the scope of library products and services is both inadequate and restrictive, wider applicability of the innovation from the education and business contexts should be undertaken.

CONCLUSION

Web 3.0 technologies and ontology have actually enabled Library 3.0 and have brought the tremendous change in the way information is now collected and disseminated. Library and information professionals are therefore expected to learn about web 3.0 technologies and ontology so as to become librarian 3.0 now and begin to offer engaging services to users. Library 3.0 does not only make users to browse and upload documents or user-generated contents but also to become co-creators of library services. Web technological applications are now encouraging participatory librarianship, but Library 3.0 goes beyond this to include value co-creation involving both the librarians or information professionals and library users in the information value chain. The simplest interpretation of this as espoused by Marshall and Shipman (2003) is that the semantic web plays vital role in helping human beings and computers to work together towards the organization and retrieval of information.

KEY TERMS AND DEFINITIONS

Cloud Computing: A model for information network, storage, and access, facilitated by a remote server hosted over the internet instead of a local server or computer.

Library 3.0: A computer-mediated library that promotes access to a wider array of information resources and services beyond its physical location.

Library Services: Information-based services offered by the library to a defined group of patrons for personal self-development, educational, business, political and other purposes with the aid of man and or technology infrastructures.

Mobile Technologies: Hand-held internet-compliant devices that foster wireless communication and computing applications using the Global System for Mobile (GSM) network which include android phones, iPhones, iPads, and tablets.

Semantic Web: A simplified world wide web that fosters human and computer interaction for effective management of data/information.

Virtual Reference Services: Electronic means of communicating and conducting referrals and other reference-based services.

Web Technologies: Mode of communication between or among interconnected computers using hypertext markup languages and other multimedia applications.

Massive Digital Libraries (MDLs) and the Impact of Mass–Digitized Book Collections

Andrew Philip Weiss

 <https://orcid.org/0000-0002-8900-2779>

California State University, Northridge, USA

INTRODUCTION

To better analyze the growth of digital libraries, Weiss and James have proposed adopting the term Massive Digital Libraries (MDLs), a concept based on the increased size, scope and scalability of mass-digitized book collections. MDLs rival physical libraries' print holdings in size, breadth, and depth, often approaching a scale previously found only among library consortia or national libraries. (Weiss and James, 2013a, 2013b, 2014, 2015; Weiss, 2016) The concept further intersects the digital library with the wider development of 'big data,' which is driven to an ever-larger scale by the '5Vs' of Volume, Variety, Velocity, Variability, and Veracity. (Weiss, 2018)

The root of the concept begins in late 2004 when Google publicly announced its intention to digitize the world's books—including works still under copyright protection—and to place them *all* (roughly 130 million) online. Jean-Noel Jeanneney, head of Bibliothèque nationale de France at the time, interpreted Google's planned project as a wake-up call for European countries. Failure to catch up to the American company, he argued, would result in significant problems for non-American organizations, especially if they were unable to check the company's outsized influence. (Jeanneney, 2005)

Fifteen years on, it is hard to imagine that Google's desire to create an online digital should have come as such a shock. Yet Google spurred significant hand-wringing and soul-searching among institutions traditionally charged with producing or preserving cultural artifacts. (Jeanneney; Venkatraman, 2009) In retrospect, the controversy seems quaint in comparison to the current crop of issues – especially the current “disruptions” of established economic models by Uber/Lyft, Facebook, Twitter, Spotify, and the like; the looming unknowns circling around artificial intelligence; and the encroachments on civil rights via electronic digital surveillance and other intrusions of privacy.

A number of similar mass-digitization projects developed and matured since Google's announcement, including the *HathiTrust*, *Internet Archive*, *Digital Public Library of America (DPLA)*, *California Digital Library*, *Texas Digital Library*, *Gallica*, and *Europeana*. These projects each transcend their roots as localized digital libraries and simultaneously adapted to and altered the digital landscape. These various MDLs have allowed for and contributed to the ascendancy of our current mass-digitization online culture.

This chapter describes the characteristics of Massive Digital Libraries (MDLs) and outlines their impact upon current information science issues, especially with regard to digital collection metadata, copyright, the diversity of source collections, and user privacy in an age of so-called “surveillance capitalism.” (Zuboff, 2015) Traditionally, libraries have been created to serve particular communities *defined* as well as *bound* by geography, intellectual disciplines, or specific end users. MDLs in their current trajectories, however, promise to transcend such limits in ways that are simultaneously *constructive* and *destructive*.

BACKGROUND: DEFINING MASSIVE DIGITAL LIBRARIES

Defining Criteria

Massive Digital Libraries (MDLs) describes a specific class of digital libraries that correspond to the size of a traditional, large brick-and-mortar library. Although other disciplines have discussed digital libraries and archives in terms of computer science, such as in the Very Large Digital Library (VLDL) movement, none have framed the discussion in terms of the principles of library science or the services and content access provided by an actual, working library. (VLDL, 2011)

The following list of characteristics has been proposed to help define MDLs:

1. Collection size: surpasses 500,000 texts; prime MDLs comprise tens of millions of texts;
2. Acquisitions, collection development & copyright: numerous partnering members contribute content regardless of author or copyright holder permissions and regardless of end-user needs;
3. Content type: mass-digitized print books; the resulting searchable digital corpus of texts becomes as important as the individual titles;
4. Collection diversity: diversity is dependent upon self-chosen partner members, which can reflect distortions or biases inherent to the source collections;
5. Content access: varying degrees of open access exist within MDLs; content is searchable through single, uniform interfaces (search engines & portals) representing all the collections as members of a single entity regardless of source;
6. Metadata: Metadata is gathered and aggregated from multiple sources, with a reliance on new digital description schema;
7. Content / digital preservation: consortium members provide long-term digital preservation strategies at local levels as well as “in the cloud”.

These criteria and their attendant issues, though not necessarily *unique* to digital libraries, require different approaches when dealt with as a Massive Digital Library. The issues involved with aggregating millions of previously published print materials into one uniform, yet decentralized, conceptual and online digital space become more complex as the size increases. It is important to differentiate MDLs from their smaller counterparts as they are more difficult to police and analyze, especially with metadata uniformity, copyright compliance, rights ownership, and user privacy. The larger an institution or system is, the more unwieldy and slow-to-change it may become. Furthermore, the lack of transparency among IT companies – especially Google – requires more robust oversight. As a result, it is important to remain cognizant of how MDLs approach the common characteristics of books in ways that stretch the boundaries of the original print medium. Print books remain static during their lifetimes, changing only when new editions are created. E-books promise the flexibility to change into ongoing “works in progress,” without fixed texts. Unlike print books, their access can easily be tracked, eroding the user privacy that remains a central tenet of libraries. Identifying MDLs as unique entities would allow scholars and researchers to both utilize and safeguard these newly-created and widely-distributed digital collections.

Representative MDLs

The following is a look at several representative MDLs and their defining characteristics. This section will also help readers get a sense of how MDLs stack up against each other. Criteria described for each

MDL include their starting dates, *modus operandi*, estimated sizes of the collections, subjects collected, the number of partner institutions, and the languages covered in their collections.

I. American-Based, Anglo-Centric MDLs

A. Google Books (25 million texts)

The *Google Books* project started in 2004. Envisioned by Google co-founder Sergei Brin as a replacement for a library's 'card catalog,' *Google Books* currently holds approximately 25 million volumes within its collections, though exact figures have been difficult to verify. Google has not provided updated statistics on its collection's size in several years, and has mostly waned in its efforts to maintain the collection. As a result, 25 million may be an inaccurate figure.

Google Books is characterized in part by its extremely robust and flexible search engine. When searching in this MDL, a large amount of set results will often appear. Mistakes in the search are often auto-corrected. Their stated goal is the digitization of all the books in the world, a number that reaches about 129,864,880. (Jackson, 2010) They work with authors directly through their Google Books Partner Program and with public organizations through their Google Books Library Project, which includes about 22 public and academic institutions and consortia from several countries, including Japan, Germany, England, and Spain. (Sato, 2010) Overall collection diversity is represented with a large number of languages represented and accessible, though the bulk of the source material in the digitized corpus is in English.

The *Google Books* corpus is open to anyone able to use a computer that is connected to the Internet. However, due to copyright restrictions and the threat of litigation, any materials falling outside the public domain have been closed to full-text viewing. Google provides users with three levels of accessibility to the texts beyond the basic metadata record: 1) Snippet View, which is a few sentences of the book, 2) Partial view, which is often several to dozens of pages, and 3) Full view, which is the complete text. Additionally, Google has provided access to the data sets from the digitized corpus for researchers to utilize. One of the most promising tools developed for this text mining is the Google Ngram viewer.

B. HathiTrust (17 million Texts)

HathiTrust started in 2008. It currently holds 17 million volumes (representing 8.2 million unique book titles) within its collections; 6.5 million volumes (38% of the total) are in the public domain. The *HathiTrust's* main goal is to meet the needs of the members of its partnering institutions. These partners include nearly 72 world-class academic research and national libraries. Notable partners include the Library of Congress and the California Digital Library. Collection development is focused on gathering digitized books and journals from partner institutions and in-house digital initiatives and those books digitized in part by *Google Books* and the *Internet Archive*.

As one might expect, English is the main language of the archive. Roughly 4.6 million of their books, representing 51% of the unique holdings, are in English. The second largest represented group is German (8.6%), followed by French (6.9%), Spanish (6.5%), Russian (3.3%), Chinese (3%), Japanese (2.7%), and Italian (2.5%). Given the large Spanish-speaking population in the United States, the small and disproportionate amount of Spanish-language materials is surprising. However, given that the books primarily come from research universities' collections, German and French (second and third respectively) have

historically represented the cutting-edge of scholarship in more disciplines than Spanish. (HathiTrust, 2019) This disparity will be discussed in greater detail below.-

HathiTrust is characterized by a robust search engine and extremely well-organized metadata and records management. Where *Google Books* has issues with the retrieval of specific dates and other types of metadata that significantly hamper its usefulness, *HathiTrust* performs information retrieval and document display with superior results. The system allows, however, only two types of views to the non-member user: 1) a limited view, which provides only search results to retrieve word counts from queries (i.e. full-text search), and 2) full-view, which provides the full text – but this is reserved primarily for materials in the public domain or those with specific author-provided permissions for open access.

Access is open to anyone able to use a computer connected to the Internet, but partnering institutions and their member users benefit from extra services such as content storage, data preservation and copy-right clearance/usage consultation. Although the current size of the collection is smaller in comparison to *Google Books*, the ability for one to find information more easily should make the *HathiTrust* the go-to MDL for *all* libraries and their patrons. Indeed, the collection size is slowly but steadily catching up to *Google Books*.

C. Internet Archive (15 Million Texts)

The Internet Archive started in 1996 as web archiving service. It currently holds 15 million volumes of texts. It is a unique addition to the Massive Digital Library category. On one hand their main focus appears to be on archiving the Internet via its *Wayback Machine*. One of their stated goals, in fact, is to create archival artifacts of the web itself, and they have archived an astounding 330 billion webpages. Unlike *Google Books* or *HathiTrust*, which focus heavily on book collection sizes, *Internet Archive's* primary concern has been less focused on the number of titles acquired. Instead, the *Internet Archive* gathers and approves *only those materials in the public domain or that have explicit author permissions*. As a result, their print-derived digital collections are slightly smaller but completely accessible.

Their advantage is also in providing links to several mass-digitization projects and allowing these projects to exist under their own names as well as within the Internet Archive web pages. Projects such as the *Biodiversity Heritage Library*, *Project Gutenberg*, the *Universal Library* and *Children's Library* are worthy open access book digitization initiatives aimed at providing people with free access to resources, all falling under the *Internet Archive* umbrella.

Their difference is also in one of scope, with their emphasis on audio recordings, video, electronic video gaming, and other unique multi-media collections. They claim to have 4.5 million audio recordings (including 180,000 live concerts), 4 million videos (including 1.6 million Television News programs), 3 million images, and 200,000 software programs in their collections. Additionally, the *Internet Archive* provides access to about 9,500 audio recordings of books, including literature and poetry. (Internet Archive, 2019)

D. Other Anglo-Centric MDLs of Note

In recent years several other U.S.-based MDLs of significance have begun to appear. The most well-known of these, The *Digital Public Library of America* (DPLA) is also one of the newest. Due to aggressive partnership and digital hub development, its growth since October 2010 has been exceedingly quick. It currently holds nearly 35 million digital items, a huge increase from the 2.5 million at its initial launch, and nearly 16.2 million texts. The collections specialize in a range of materials from books to

digital archives. The scope ranges from materials for students and teachers at the K-12 level, and for universities up to the graduate-student level. The main partnering institutions include public libraries, university libraries, historical societies, museums, and archives. It is now a major up-and-coming MDL and has clearly learned from the negative experiences and outcomes of its predecessors. (DPLA, 2019)

Additionally, the *California Digital Library* and *Texas Digital Library* continue to grow. Although they serve more localized, state-based interests, their open online accessibility ensures widespread impact. Many of CDL's digital book collections appear as subsets within Google Books, the HathiTrust, DPLA, and Internet Archive. (CDL, 2019) The Texas Digital Library's collections focus on large-scale institutional repository development and issues inherent to scholarly communication, especially ETDs, data management planning and archiving, digital preservation and digital objects. (TDL, 2019)

II: NON-ANGLO-CENTRIC MDLS OF NOTE

A. Europeana (58.7 million Items / 12.1 Million Texts)

The *Europeana* digital library aggregates multi-media content from nearly 240 institutions across Europe, including video, image, text and digital artifacts. It is a multi-lingual, multi-cultural endeavor. There appears not to be one dominant language in the project. With a huge collection of over 12.1 million texts the digital library should be considered a leading MDL in the field. (Europeana, 2019) Their emphasis on interoperability and a strong metadata schema allows users to refine searches and hone in on more relevant search results easily. The main focus for the library is to ensure that digital materials of numerous cultures remain freely accessible to all. The project advocates the strongest pro-Public Domain stance of nearly all the MDLs. (Fallon, n.d.) It is a vital and important MDL as a result.

B. Gallica (5 Million Items / 695 Thousand Texts)

Despite its smaller book collection size (less than 1 million), *Gallica* is noteworthy for several reasons. One, it was the first digital library developed in direct response to the Google Books project. (Gallica, 2019). Two, it is primarily and uniquely a France-centric, Franco-phone Massive Digital Library. Its partners include many universities and museums in France but also the National Library of Brazil and the Library of Congress. There are books offered in English and other languages, but it is a small amount compared to the size of the French language collection. *Gallica* is also, in many ways, an MDL counterpoint to *Google Books*, with a very different philosophy and approach to the digital library.

III. MAJOR ISSUES AND CONTROVERSIES

A. MDLs, Mass Aggregation & The Accuracy and Veracity of Results

Google Books' policy for developing their Massive Digital Library appears to have been very simple: *digitize everything*. Such ambition to collect all of the world's knowledge is not unheard of in the history of libraries, yet these are time-consuming and costly efforts requiring extreme amounts of funding and personnel to do them adequate justice. It is as ambitious as it is unrealistic. It is possible complete digitization may never happen as new books are still being published in print form yearly. Furthermore,

not all books are available with digital counterparts or can even be scanned accurately and adequately. Some works made with high-quality materials, odd-sized or hand-crafted paper, or three-dimensional forms, are preferable to many readers as solid objects and not as screen-bound 2D digital copies. Some countries such as Japan have traditional binding procedures that are unique and not easily transferrable to digital formats.

The estimation of 129 million books may also be flawed. Relying on ISBN numbers is not accurate as many countries did not adopt ISBNs until the 1960s or 1970s. The differentiation between serials, multi-volume works, multiple editions and the concept of “books” is unclear as well. For example, does Google consider the numerous volumes of the Harvard classics as one book series, with one record as in a library catalog or the Hathitrust, or are they conceptualized as separate books? Does the second edition of volume 13 of the Harvard Classics count in the tally if the first edition is available? Furthermore, is it vitally important to have a scanned copy of every edition of a classic text? A “digitize everything” approach does not suitably answer these questions and an assumption of universality becomes a disservice to all.

Endeavoring to digitize all the books is not so much a collection policy as it is an *avoidance* of one on a massive scale. The results are akin to a typical Google keyword search: a mixture of high and low culture with only relevance ranking, which can be manipulated by both black and white hat Search Engine Optimization (SEO), to determine whether it is a satisfactory result. One concrete example of this issue has been the inability for the Google Books search engine to accurately retrieve and coherently display single works of multiple-volume book series. A search for <Harvard Classics> results in a jumbled non-sequential retrieval of titles. Unless one had known before-hand that the *Harvard Classics* series contains 51 volumes, one might never get an accurate accounting of the texts from Google’s set result.

At the same time, digitizing all content will also include books of questionable natures, including the literatures of hate, pornography, and other provocative or even dangerous materials. Yet, despite their intention to digitize everything, it is unclear due to Google’s secrecy whether they have digitized materials that are hateful or offensive to various groups.

One must be wary of this approach as well, because not only will books be missed, especially those not held by Google’s Partners, but also a lot of unnecessary, spurious, or poorly written materials will be added to the collection. This in turn dilutes the rationale for collecting something.

Additionally, the accuracy of the metadata needed to track and provide information retrieval in meaningful human-readable ways is also at risk. James and Weiss (2012) found a high rate (36%) of errors in their study of Google Books’ metadata. Other scholars have been pointing out the “train wreck” that is Google Books’ metadata for quite some time. (Duguid, 2007; Nunberg, 2009) Weiss and James also examined rates of error among metadata and in scanning results. James (2010), Weiss and James (2013a, 2013b, 2014, 2015), and Weiss (2016) have found significant evidence of errors in Google Books.

All of these issues – from responsible collection development and content aggregation to the accurate retrieval of information – are intertwined. Including reputable and appropriate sources, accurate information, and verifiable content instills trust in users, something traditional libraries have done very well. Google Books, on the other hand, has struggled with this. Without trust, users will eventually abandon the service.

B. MDLs & Copyright

MDLs have greatly impacted copyright law. MDLs can be seen as logical extensions of the Internet’s early promise of the information superhighway and the democratization of knowledge. Yet there has been intense backlash from all sides against MDLs. Indeed, the two largest of the Massive Digital Libraries,

HathiTrust and *Google Books*, were saddled with high-profile lawsuits for years, both initiated by the Author's Guild, from the mid-2000s until 2015.

By November, 2013, Google's long legal fight eased somewhat with the ruling in Google's favor by Judge Denny Chin. (Lee, 2013; Chant 2013) By 2014 appeals were also found in favor of the HathiTrust over the Authors Guild. (Chant 2014) By the end of 2015 Google's case had been resolved with the United States Second Circuit ruling in the fall of that year in favor of the tech giant, and the U.S. Supreme Court declining to examine the case further. (Hurley, 2016)

Looking at it more objectively, though, Google's legal problems stemmed from the proprietary nature of their endeavor. If they had been willing to abandon some of the profiteering and posturing, or to alter the purpose of their program, the project might have been seen in a better light by the Authors Guild. Despite Google's controversial approach, however, the U.S. Supreme Court considered the project to fall within the guidelines of fair use, especially regarding the ultimately transformative use of the source material. (Hurley)

HathiTrust, in contrast, weathered the copyright lawsuit storm quite well and remains poised to develop as the leader of MDLs in terms of copyright compliance and providing accessibility to the disabled and access to public domain works. The result of their lawsuit showed that the fair use defense remains a strong one as long as it is coupled with such factors as restricting access to copyrighted work and remaining non-profit in nature. Their digitized corpus was also ruled fair use because of the importance the *HathiTrust* placed upon providing works with greater accessibility for the disabled. The fair use defense also made it clear that the *scope* of a project, which the Author's Guild had criticized, is irrelevant. Fair use holds in principle regardless of the number of books they digitized.

Among other MDLs, *Europeana's* efforts in advocating for a strong and robust public domain make it a worthy cause to follow. (Fallon, n.d.) It is hoped that they continue to fight for strong and clear open access of cultural content disambiguated from the profit motives of the corporations that tend to own the lion's share of copyrighted material.

C. The Promises and Pitfalls of Diversity

Google Books' partners have included institutions in Spain, Germany, France, and one university in Japan. Given the huge number of books, languages and cultures in the world, one must consider deeply whether such limited partnerships are feasible and scalable. In order to have complete universal coverage, one would need to add partners from everywhere, including institutions devoted to sub-communities and sub-cultures within larger countries. But despite such ambitions to create a digital corpus of everything printed, it is likely not a realistic outcome.

Furthermore, the act of scanning itself causes distinct issues. As Thylstrup writes, once a decision is made to digitize content, scanning becomes a political act rife with "distinct subpolitical processes." (2014) In addition, researchers have found that the contents of the Google Book corpus do not represent an unbiased sampling. Pechenick, et al. argue that "the evolution of the corpus throughout the 1900s is increasingly dominated by scientific publications rather than popular works. We have shown that even the first data set specifically labeled as fiction appears to be saturated with medical literature." (2015) Aside from the problem of misrepresenting common collections, or transforming the boundaries of traditional print forms, the selection of texts appears to be skewed in favor of scientific titles. Weiss and James find missing public domain books in the Google corpus and a low representation of Spanish and Japanese language texts. (2013b, 2015) The diversity of content in the *Google Books* project as well as any of the other MDLs, therefore, remains at the mercy of the partnerships they have created.

For the *HathiTrust*, similar issues exist. The number of partners is large, but still not comprehensive. According to their online statistics, the percentage of English language books remains at about 50%. Of the top ten languages, 60% are Indo-European, with one, Latin, being a dead language. Two are East-Asian Languages (Chinese / Japanese) and one is a Slavic language (Russian). (HathiTrust, 2016) By world population and the number of cultural artifact created by various cultures – especially those that are older than the United States by millennia – the collections are disproportionately skewed toward the English language. Again, like the *Google Books* project -- and in part because many of the *HathiTrust* partners as well as digitized books are shared with *Google Books*--the issue of the source materials calls into question the ability of MDLs to create collections reflective of an increasingly diverse population.

For Public Domain works, this proportion skews even further to English - about 60 percent of titles in the public domain are English with 40 percent left for any other language. Generally, this reflects the needs of the faculty and students at the academic institutions currently partnering with the *HathiTrust*. It is quite telling that the second and third largest collections of works are German and French, while Spanish, the second most-spoken language in the United States, trails at a distant 4th. Only 6.5% of the HathiTrust's online collection is in Spanish, yet 36 million people (roughly 12% of the population) in the United States speak Spanish as their *first* language. In contrast, only about 1.3 million (or .41%) speak French and only about 1.1 million (about .35%) speak German, yet the HathiTrust collections include 7% and 9.2% of these languages respectively. (US Census Bureau, 2011)

It is clear, then, that subject diversity could be better addressed by even the MDL exemplars. It is hoped that as these digital libraries develop over time, the gaps found in their coverage will adapt to the new, at-large audiences that exist beyond the physical boundaries of the locations they represent.

D. Privacy and The MDL

Finally, one of the under-examined issues regarding Massive Digital Libraries is the problem of ensuring and safeguarding user privacy. User privacy is one of the pillars of library policy, especially regarding the subject matter that users search for. Safeguards exist locally, regionally, and nationally in terms of information, especially with medical and student information (i.e. HIPAA, FERPA). Libraries follow this as well with local user policies that are backed up or enforced by guidelines from state and national library and archive organizations. The American Library Association, for example, provides clear policy for libraries nationwide, regardless of their constituencies. (ALA, 2014)

While HathiTrust, DPLA, CDL, and TDL closely follow privacy policies supported by the ALA, the same cannot be said for Google. Indeed, one of the main issues with the tech company has been its well-publicized disregard for how user data is handled. After it is collected, it is often shared or sold to third-parties for advertising revenue. This type of “surveillance capitalism” as defined by Shoshanna Zuboff, greatly compromises the benefits the Google Books corpus provides for researchers and users. It is unclear how or to what extent Google has shared or sold the data about its users of the Google Books database, but doing so flies in the face of a century of modern library practice. Big data surveillance meets the digital library.

IV. SOLUTIONS AND RECOMMENDATIONS

Regarding the problems of faulty scanning, digital representation and verisimilitude, it is likely that improved algorithms and AI for image correction may improve the problems related to book digitization.

AI may also be used to help with improving the rates of error in metadata associated with the books. In the case of Google Books, they would be well-advised to drop the BISAC-derived subject headings, which are used by booksellers and not libraries, and take efforts to use the metadata and controlled vocabularies developed by libraries over decades of intense and precise practice. This might help with improving the generally dismal experience of Google Books.

Google's cavalier approach to copyright should be taken as a cautionary tale. HathiTrust's approach to copyright, rigorous checks and adherence to copyright permissions, on the other hand, *should* be emulated by all MDLs. Their innovative copyright clearance project uses hundreds of volunteers to manually research and double-check the copyright status of many orphan works. While it is a widely-known rule of thumb that a book published prior to 1924 is in the public domain, it is less well-known that many works published after 1924 may actually be in the public domain as a result of various factors, including non-compliance with rules and failure to re-register a work after its initial copyright period. The HathiTrust's copyright verification project carries out the due diligence necessary to make sure scanned works can be released to the general public. Notably, U.S. copyright law in January 2019 finally allowed new works into the public domain after a twenty year freeze. MDLs will be well-advised to open these previously closed works. Each year after this, works will be released.

Finally, libraries and MDLs need to be advocates for and practitioners of stronger online privacy laws. Current user-tracking practices erode online privacy for the sake of profits derived from the basic tenets of "surveillance capitalism," which "exile persons from their own behavior while producing new markets of behavioral prediction and modification." (Zuboff, 2015) The dampening impact of surveillance on information-seeking behavior cannot be underestimated. MDL governance structures and governing bodies will need to be vigilant advocates for better privacy safeguards, especially as Google and Google Books continue track users' every move. The European Union's *General Data Protection Regulation* (GDPR) is a good first step, but more widespread policies across all nations must be adopted.

V. FUTURE RESEARCH DIRECTIONS: THE IMPACT OF DIGITIZED BOOKS

A. Humanities and the Ngram Viewer

One important impact that MDLs can have on current scholarship is the mining of the immense data sets generated from the mass digitization process. The Ngram viewer, designed by John Orwant and Will Brockman at Google, provides data visualizations for the frequency of queried terms. This is a helpful tool for not only historians, writers, artists, and social scientists, but also libraries. (Google N-gram, 2016) Michel, et al. (2011) have shown the impact that research in this area, which they have called "Culturomics," can have on scholarship and textual analysis. Additionally, one can track historical events in the news or the ideas and concepts that accompany them. It is truly a useful tool for those interested in the history of ideas and how events shape them.

In the example shown in the figure above, a search involving the terms <Hiroshima> (in blue) and <Nagasaki> (in red) was conducted by the author. The search results show the frequency with which the words appeared in the English language from the period of time from 1800 to 2000. For the first 140 years, Nagasaki was the more mentioned of the two cities, likely a result of it being the only port open to foreign trade during the closed-country *sakoku* period in Japan. During the 1850s-1860s, Nagasaki also began to surge, likely a result of the United States' aggressive policies to "open" up the country to international trade. Again a surge occurred between 1900 and 1910, reflecting its status as a major hub for coal production and the Japanese Navy's winter port for the Russian Asiatic fleet.

Figure 1. Ngram viewer showing frequency of the names Hiroshima (blue) and Nagasaki (red) from 1800 to 2000. Note the significant change starting in the early 1940s and spiking post-WWII.

Hiroshima during this same period of time is not mentioned very much in comparison, trailing at a very distant second. However, during the years after the bombing of Pearl Harbor, Hiroshima becomes ever more frequently mentioned. Only by 1944, a year prior to the atomic bombings of both cities, do Hiroshima and Nagasaki reach parity in terms of frequency. After 1945 until the present day as a result of being the first city to suffer an atomic bomb attack, Hiroshima has been mentioned the most.

It is a useful tool for students to get a better sense of the context of historical events and an understanding of how notoriety waxes and wanes over time. It becomes clear then that MDLs can offer more than just digital versions of books and get at assisting not only scholars but also interested lay-persons, librarians, and students. The ability to search for concepts across a large sample of materials will revolutionize the humanities, the history of science, and even science itself, as people begin to see the patterns in knowledge development and information retrieval.

CONCLUSION

The Massive Digital Libraries covered in this chapter show striking individuality in their approaches to mass-digitization and the mass-distribution of digitized content. Yet many of their defining characteristics – from size to content aggregation, to development of consortiums and to content diversity and general accessibility – nonetheless remain similar. Their central missions to share the content of print books that may be locked away in print on physical book shelves are also admirable. Varying degrees of scope, subject matter and audience involvement shape these massive collections in individual ways, making each MDL unique.

Overall when looking at the main examples of MDLs currently in existence, one gets the sense that ambitions for a “unified digital front” for all types of materials is the impetus driving their development. This ambition impacts brick-and-mortar libraries in that they may have to scramble to accommodate as well as take advantage of these growing initiatives.

The issues raised by MDLs speak directly to the issues at the heart of mass-digitization culture. Veracity, accuracy and diversity get at the essential quality of any information society: trustworthiness. If one is able to trust the quality and comprehensiveness of these mass-aggregated collections, then MDLs will provide an essential service to the pluralistic and democratic societies from which they have sprung. Additionally, the issues of copyright are providing a lesson to all on fair use and the development of new open access/open source cultures dependent upon the alteration and recombination of previously created works. Privacy needs to be guarded for the user, however; otherwise, users will rightly see MDLs as intrusive tools that have the ability to oppress those searching for unpopular or controversial ideas. The new tools and applications of MDLs, such as the Ngram Viewer, despite some of the issues of representation existing at the heart of the Google Books corpus, promise to augment the value of individual books beyond their physical limitations. MDLs will ultimately provide users with enhanced approaches to existing disciplines as well as the promise of new transformations.

KEY TERMS AND DEFINITIONS

Big Data: The large-scale aggregation of data from software and wired devices, used for the purposes of analyzing systems or user behavior; it is characterized by its large volume, wide variety, velocity (or speed of transfer), its increased variability, and undetermined veracity.

Digital Corpus: The full text of millions of books digitized by the MDLs. These provide opportunities for scholars to examine the frequency of terms as they appear in the print corpus.

Digital Humanities (DH): A branch of the humanities incorporating digital search, digitized texts, encoding, and other strategies to move previously print-bound materials and scholarship into computer science related analysis.

Fair Use: Defined by some as the breathing room to allow for the freedom of expression, it is a strong limitation of the extent of copyright law. It is determined by examining four factors: 1) the purpose and character of the use; 2) the nature of the copyrighted work; 3) the amount and substantiality of the portion taken; and 4) the effect of the use upon the potential market.

Mass-Digitization: The practice of quickly and thoroughly digitizing items on a large scale. In the case of MDLs these efforts involve scanning millions of books with multiple institutional partners across national boundaries.

Massive Digital Libraries (MDLs): Term adopted to describe the mass-digitization of printed books and the mass-aggregation of their metadata into online, full-text-searchable digital collections; some component of open access and use of public domain works defines their collections; diffuse and diverse target end-user groups are also characteristic of MDLs.

Ngram Viewer: A tool developed by Google to aid in the visualization of the digital corpus of books. It plots frequencies of terms across a graph, helping users understand how common a word or concept was in the corpus at a specific moment in history.

Public Domain: Works that are no longer under copyright protection. In the United States these works tend to be those published before January 1, 1924 and unpublished works created prior to 1899. U.S. Government publications are in the public domain.

Surveillance Capitalism: A term coined by Shoshanna Zuboff to describe practices of monetizing data derived by companies tracking online users of various services and devices.

INTRODUCTION

Clinical research is a branch of medical science which deals with any research or study in living humans. Clinical research is a process consisting of pre-clinical testing of newly developed drugs and filing of Investigational New Drug Application (IND). Phases in clinical trial involves three phases. Phase I is for assessment of safety of drug. Phase II involves effectiveness testing. Phase III is for large-scale testing, approval to use new drug i.e. licensing, approval of drug and post-marketing surveillance for reporting of any other adverse events. (Manavalan and Sinfield, 2017; Thorat, et. al., 2010; Gandhi, 2011)

Clinical research involves systematic investigation for treating the diseased conditions, overall health improvement and longevity of human. This involves volunteer participants for biomedical research with scientific guidelines. The research is conducted with pre-defined procedures, investigations are carried out carefully and outcome is recorded. The ethical principles are strongly utilized for protection of identity of participants. The clinical research allows identifying new curative and preventive ways to understand the prognosis of disease, diagnose and treat the diseases in human. (Thorat, et. al., 2010; Gandhi, 2011; Bajpai, 2013).

CLINICAL RESEARCH

Clinical trial is a research study, also called as clinical study. This study includes testing of new treatments or modification of existing therapy on human volunteers. The study determines the safety and efficacy of drug therapy for commercial use in various populations. They provide better way to screen, diagnose, prevent and cure a disease. Clinical trials are carried out for the new treatments under research whose outcome is unknown and previously not studied. Clinical trials follow a pre-designed plan for health-related research studies in human. Clinical trial is defined as the systematic study of new drugs in human to generate data for discovering and verifying the clinical, pharmacological and adverse effects with objective of determination of safety and efficacy of the new treatment. (Bajpai, 2013; Manavalan and Sinfield, 2017)

Research team in clinical trial includes doctors, nurses and health care professionals. They monitor participants and do their health checkups regularly. The research team works with participants in all

DOI: 10.4018/978-1-7998-3479-3.ch124

types of trials. Role of participants or volunteers is more active in clinical research. They are important as they get new therapies to treat a disease before these are available for commercial use. For the safety of volunteers or participants involved in clinical research, there are guidelines for appropriate selection. After qualifying the eligibility criteria they can take part in clinical trial. (Crisp and Burke, 2005; Gandhi, 2011).

The plan with all details of the clinical trial is called as research protocol. Every study has different protocol depending upon type of trial. If the protocol is carefully followed during the clinical trial process then trial becomes more successful. Design of trial plan takes care of safety of participants. So, the research protocol should be designed carefully. The protocol describes all the details of the study. (Thorat, et. al., 2010). Figure 1 represents general flow for study of the drug throughout clinical research.

Figure 1. Representation of clinical research and phases of clinical trial (Source: Thorat, et. al, 2010)

CLINICAL TRIAL PHASES

Preclinical trial study is done on laboratory animals before testing the drug on human. This testing determines safety of drug for human consumption in disease treatment. After completion of preclinical study, filing of an investigational new drug application (IND) must be done. (Thorat, et. al., 2010; Gandhi, 2011).

Phase I study is carried out on 20-80 healthy human volunteers. It determines the safety, pharmacological actions including adverse effects, drug dose and tolerability. The drugs used in the treatment of life-threatening diseases are not studied in this phase. Phase II is carried out on 100-300 patients meeting selection criteria called as volunteers or participants. It is aimed for safety, efficacy and effectiveness of the drug and determines the therapeutic potential of the drug. It also reports the adverse effects of

the drug. Phase III is carried out on around 1000-3000 participants. It is aimed to investigate safety and efficacy of drug at large number of population. Once it is confirmed that the research drug is safe and effective, a New Drug Application (NDA) is filed for approval of use of drug. The regulatory authority reviews the application and approves the drug. After approval, the drug is marketed and healthcare professionals can prescribe it. The regulatory authorities can review the drug effects at any point of time to ensure safety and effectiveness of the drug, after it is released in market for variety of population. These are Phase IV clinical trials which are also called as post-marketing surveillance. Thus, clinical trials ensure that a new drug or device or treatment is beneficial for the patients involved in the research for the diagnosis and treatment of the disease. (Crisp and Burke, 2005; Manavalan and Sinfield, 2017; Silverman and Kwiatkowski, 1998 ; Sipido, 2014).

If the participants or volunteers want to take part in clinical trials, they can directly search ongoing clinical trials on ClinicalTrials.gov by use of a registry channeled by the U.S. National Institutes of Health and National Library of Medicine. The clinical trials in India are regulated by the drug & cosmetics rules, 1945. Schedule Y along with rules 122A, 122B, 122D, 122DA, 122DAC and 122E governs clinical trials in India. (Mondal and Abrol, 2015). The Ministry of Health and Family Welfare (MoH and FW) controls Central Drugs Standard Control Organization (CDSCO) operations. CDSCO specifies the standards for clinical trials in India which ensure the safety and efficacy of trial drugs, diagnostics and medical devices. ClinicalTrials.gov currently lists 312,117 studies with locations in all 50 States and in 209 countries. (CDSCO- Amended Version -2005; Saxena and Saxena, 2014 ; Gogtay, 2017)

Currently, India is conducting 3,758 clinical trials. The registration of clinical trials carried out in Clinical Trials Registry of India (CTRI). Total number of clinical trials registered in India increased from 859 in 2015 to 3869 in 2018. (Dieppe, et. al. 2004). Figure 2 represents increasing number of registered clinical trials worldwide from the year 2000. Table 1 summarizes the percentage of registered studies location wise (as of July 25, 2019) for total number of 312,117 clinical trial. Figure 3A pie chart is a graphical representation of the distribution of clinical trials by location which is registered on ClinicalTrials.gov. ((Mondal, & Abrol, 2015, Sengupta, 2009, Lahiry, et. al., 2018).

Figure 2. Total number of studies posted since 2000 (Source: <https://clinicaltrials.gov>)

Table 1. Percentage of registered studies location wise

Location	Number of Registered Studies and Percentage of Total
Non-U.S. only	151,622 (49%)
U.S. only	106,874 (34%)
U.S. and non-U.S.	16,453 (5%)
Not provided	37,168 (12%)
Total	312,117 (100%)

(Source: <https://clinicaltrials.gov>)

Figure 3. Percentage of registered studies location wise (Source: <https://clinicaltrials.gov>)

Companies like Syneos Health, IQVIA, Paraxel International Corporation and PRA Health science are leading in clinical research sector. (Bhave and Menon, 2017). Table 2 summarizes some Indian companies with research drugs which conducted clinical trials with a positive research outcome for a specific indication with successful U.S. FDA approval and marketing of drugs. (Manavalan and Sinfield, 2017; USFDA, 2010)

Table 2. List of companies with study drugs and Indication approved by US FDA (Source: Manavalan and Sinfield, 2017).

Company	Compound Researched	Indications
Cangene	HepaGam	Hepatitis B
Eli Lilly	Alimta	Cancer
Eli Lilly	Cialis	Erectile dysfunction
Eli Lilly	Xigris	Septicemia
Janseen	Risperdal	Psychosis
Novartis	Zelnorm	Irritable bowel Syndrome
Pfizer	Vfend	Fungal infections
Wyeth	FluMist	Influenza
GlascoSmithKline	Lamictal	Epilepsy
Alcon	Vigamox	Ophthalmic infections

CLINICAL TRIAL STANDARDIZATION

For standardization in the study process there are several documents ensuring that all the staff is working in the same way. These documents have prime importance in clinical research especially if the trial is multisite. The standardized trial is also considered as ethical study with valid data. The documents like investigator's brochure, operations manual, standard operating procedures (SOPs) and research protocol ensure the study is going in standardized manner. (Sipido, 2014; Gandhi, 2011; ICMR, 2006).

The investigator's brochure contains clinical and non-clinical data derived from previous experiments. The operation manual provides detailed procedures required in the actual research. The standard operating procedures (SOPs) describe detailed specific procedures. Most SOPs are identical for all trial study sites. All staff should be trained properly for all procedures involved in the study. The research protocol describes a plan in detail for the essential aspects of the proposed study. (Gandhi, 2011).

BACKGROUND

Clinical Trial Protocol

Clinical trial is conducted as per the predefined action plan. After design, complete planning of the study, the plan should be written step wise in proper manner. This plan is called as study/ research protocol explaining the study methodologies in detail. Every clinical study has its written protocol. Depending upon the type of clinical research the complexity of protocol varies. Thus the development of protocol is an important step. If the study is multisite then the protocol should be more elaborative to avoid the risk. A protocol should be designed and written carefully for the health benefits and safety of the participants involved in the study. ((Mondal, & Abrol, 2015, Patel, et. al., 2019).

Protocol writing is a collaborative effort by a team which makes sure that the scientific procedures are practically applicable. A well written up protocol gives good study design and a guiding line for the staff involved in the research to conduct the study properly. It should clarify the thinking process of investigator and purpose of the study clearly. The success of the study trial depends on the protocol so the researchers should add every minute detail of methodology in it. (Christina, 2015, Al-JunDi, & Sakka, 2016).

There are some benefits of good protocol to investigators and other staff. Protocol acts as a detailed guide throughout the study. It allows staff to plan accordingly, the steps and review them. It helps to the researchers to adhere to timeline and budget estimates. The principal investigator is a doctor who leads the protocol designing. During the protocol development investigator can take beneficial advices from experts and other staff to refine the plan and procedures. (Bagatin, et al., 2013).

A protocol provides evidence for the prerequisite and feasibility of a study in written form. A research protocol is a document containing all the details about the background, need of study, aim, methodology, data management, ethics, time and finance of a clinical research project. The researchers should mention various components of the study including trial procedure, study monitoring, data collection methods, outcomes, statistical approaches and analysis of results etc. A protocol decides the eligibility of the participants in the study. It gives detailed information about the drug dose, frequency, tests procedures, period to which study should be carried out. The protocol information should be clear, easy to understand by another investigators and staff. It should be explained in detail to answer any question related to research. (Christina, 2015 ; Eaton and Santini, 2007).

After the completion of development and approval of the protocol, staff should strictly follow the protocol during the study. Violations of the procedures may reflect badly on the complete study data and results. The violated part of the study can be excluded during analysis of data and results. After completion of written protocol, it should be reviewed by the suitable persons. The protocols are lengthy and complex with numerous steps of scientific methods involved. To avoid any mistakes, the review of protocol should be more than once. The team of staff involved in the study should regularly monitors the medical and behavioral conditions of the volunteers in the study. This monitoring ensures the safety and effectiveness of the protocol. (O'Brien and Wright, 2002;Christina, 2015).

Figure 4 represents the importance of clinical study protocols and the associated beneficiaries.

Figure 4. Importance of clinical study protocol

(Source: <https://irb.research.chop.edu/protocol>)

PURPOSE OF A CLINICAL TRIAL PROPOSAL (Sipido, 2014)

- It highlights the importance of the research.
- It provides objective and suggest methodology in detail to achieve the objectives.
- It clarifies the hypothesis of research.
- It highlights the benefits, limitations and demands to achieve the objectives.
- It provides detailed ethical considerations.

NECESSITY OF CLINICAL TRIAL PROTOCOL

The clinical trial should be novel and ethical. Successful clinical trial run depends on the relevancy of trial to its objective, interest of the investigator and staff to adhere to the guidelines, feasibility to carry out all steps without error. It provides transparency about the procedures to everyone involved in the clinical study. (Christina, 2015; Al-JunDi, and Sakka, 2016).

Incomplete protocol leads to ambiguous procedures and inconsistent results, thus many problems may arrive during research trial. For high quality clinical research studies a complete and well written protocol play a vital role. A carefully planned and well written protocol helps to conduct and complete

clinical trial smoothly. To avoid any issues during the trial run, it is necessary to spend some time initially to write a detailed protocol before the trial begins. (Eaton and Santini, 2007).

WRITING A GOOD CLINICAL TRIAL PROTOCOL

A good research protocol should clearly highlight the aim and objective of the study which helps investigator to stick to the purpose. It should answer every question raised by the investigator and other staff involved. It should explain the procedure of every step in detail, involved in the research to carry out the trial. This will avoid any confusion and errors during the trial. The scientific challenges, practical applicability of the procedures, regulatory guidelines and reporting timelines should be addressed in detail.

Detailed literature survey is must to define a research problem and to formulate aim and objective of the study. It should clearly define the study population, eligibility criteria for the participants and research outcome. Sample size and statistical calculations should be defined. Timelines for review, monitoring, audits and reporting should be predefined. (O'Brien and Wright, 2002 ;Christina, 2015;Hulley, et. al. 2001)

After completion of writing of protocol and before starting the research study, the designated Institutional Review Board (IRB) must approve the protocol. There is requirement of clinical trial approved protocol for fulfillment of ICH-GCP guidelines. Title 21 Part 312 of the Code of Federal Regulations (21 CFR 312) narrate that a research protocol and its amendments for clinical studies are managed under an Investigational New Drug (IND) application.(ICH guidelines, 2016; O'Brien and Wright, 2002;Christina, 2015). Figure 5 represents the steps involved in clinical trial protocols.

Figure 5. Components of clinical research protocols

CLINICAL TRIAL PROTOCOL CONTENT

(Bagatin, et al., 2013; World Health Organization., 2014;Rodger, 2015;ICH guidelines, 2016; Al-JunDi and Sakka, 2016; O'Brien and Wright, 2002; Christina, 2015).

A protocol should explain the following points in details as per ICH- Good Clinical Practice (GCP):

- Title Page (General Information)
- List of Abbreviations
- Background Information
- Objectives/Purpose
- Study Design
- Selection of Subjects
- Treatment of Subjects
- Assessment of Efficacy
- Assessment of Safety
- Adverse Events
- Direct Access to Source Data/Documents
- Data Handling and Recordkeeping
- Data Management
- Statistics
- Follow-Up
- Strengths and limitations
- Quality Control and Quality Assurance
- Expected Outcomes of the Study
- Ethics
- Budget
- Publication Policy
- Project Management
- Conflict of Interest
- Timeline
- References
- Annexure
- Supplements

DETAILED CONTENT OF CLINICAL STUDY/RESEARCH PROTOCOL

Title Page and General Information

Title page and general information section should include the content summary with administrative details of the protocol. The title of the study trial should be informative, concise and reflect the study details. This section should include following details:

- Title of research protocol with protocol number
- List of content: divided in section and sub-sections accordingly
- Name, address and signature of the authorized team member with date, approved version number of protocol
- Name and address of the sponsor or funding agency
- Name, title address and telephone number(s) of the investigator(s) with responsibilities

- Name, title, address, and telephone number(s) of the qualified physician
- Name, title, address, and telephone number(s) of all the staff or team members involved in trial
- Name, address and telephone number(s) of the research site(s)
- Name(s) and address(es) of the clinical laboratory(ies) and other technical service providers

List of Abbreviations

This section should enlist with the abbreviation used in the study protocol.

Background Information

This section gives detailed information about the scientific reason for the research problem for a particular protocol. The scientific literature survey and justification of the selected research should be mentioned in this section. Introduction should be in a sequential manner. It should contain a name and description of the investigational product(s). It should also contain a summary of the research protocol. It should be clear, concise, includes a significance of research and all important aspects of the protocol like aim and objectives, number of participants, methodology, timelines and expected outcome. The literature survey should state the rationale of the research. The aim and objective of the protocol should be in continuation with the significance of the research mentioned in the literature review section. It should give the answers to all possible questions related to selected clinical research.

Objectives / Purpose

This section includes the aim and objectives of the selected clinical research problem. The description of the objectives and purpose of clinical research should be simple, clear, detailed, easy to understand, specific to research problem. The purpose and objectives of the research protocol should be logical, sequential, realistic, relevant to the research problem emerged from the literature review. It should be feasible, time based and not to be over ambitious. Major and minor objectives should be described in this section of protocol.

Study Design

This is most important part of protocol. This section describes the design of the study and detailed procedures involved in research trial in stepwise manner. This should include detailed information regarding study site, participants, detailed methodology, sample size and observations. The study design should be in relation to the objectives of the study trial. The inclusion and exclusion criteria for eligibility of participants depend on the type of the study and should be defined properly.

The details about the observations to be checked should be mention in this section with techniques and procedures to note the observations, the time period and frequency to which the observations need to be made. If the observations are in format of questionnaire, then it should be attached to the protocol in the end. All laboratory or diagnostic test procedures should be mentioned in detail. (Noordzij, et. al. 2009)

The sample size of the research is the indicative of the target/ selected population and should be previously defined and justified. The basis on which sample size has been decided should be included in this section. A larger sample size increases the time required for the study completion and cost of the study. The utilization of large number of subjects to test the research hypothesis and conduct the study trial is

not ethical. The smaller sample size can be studied within short period of time. It should be economical and ethical. Small sample size also can be unethical if exposed to risk without understanding of science.

Selection of Subjects

This section describes the selection and withdrawal of subjects or participants in study trial i.e. the inclusion and exclusion criteria for participants. This is important part of protocol as it provides information on eligibility criteria for the subjects. This should highlight all the appropriate selection criteria like age, sex, type of underlying disease, medical history, and other medical conditions. The eligibility criteria help in practical applicability, safety issues of participants and meeting to the regulatory guidelines. If criteria are not well written, the validity of outcome of the study trial may affect.

Eligibility Criteria Should Have:

- Number of eligibility criteria should be minimum
- Criteria should ensure the safety of the patient and correct scientific knowledge
- Criteria should be clear, well defined for easy to understand.
- Criteria should be verified by an auditor.

Failure to write eligibility criteria properly leads to failure to imitate clinical practice. It may increase complexity and costs required for the study. It may also lead to reduced number of recruitment of participants involved in study.

Treatment of Subjects

This section includes all the detailed information regarding treatment given to the participants. This contain the name(s) of drug, drug dose(s), dosing frequency (ies), the route (s) of drug administration for all the product(s) used in the treatment and follow up schedule(s) for participants for each product involved in the trial.

Assessment of Efficacy

This section provides the specifications of the parameters for efficacy study. This should describe methods for record, assessment, and analysis of efficacy parameters. Overall this highlights effectiveness of the study.

Assessment of Safety

This section describes the specifications of the parameters of safety for the study. It describes the expected side effects and adverse effects of the associated study drug. The detail reporting of adverse effects to the sponsor and regulatory authorities should be done. The follow up requirement after adverse events should be mention. This should detail the procedure to deal with and after adverse events. This should describe methods for record, assessment, and analysis of safety parameters.

Direct Access to Source Data/Documents

This section describes the permission from investigators to directly access the collected data for periodic monitoring, review, audits, and review by institutional review board (IRB) and inspections by regulatory agencies.

Data Handling and Recordkeeping

This section of protocol should provide information of methods of data collection, data handling, data management and storage. Some data collection tools are like questionnaires, structured or semi-structured interviews, medical records, results of laboratory tests, other clinical examinations etc. The data can be stored in computers for analysis. Further the collected data can be monitored, verified and reviewed to summarize in research outcome. The data coding in computer systems should be mentioned in the protocol. The statistical methods used should be predefined to carry out analysis of the collected data.

Data Management

A detailed data management plan should be mentioned in this section. A general description for data management for protocol should be provided. The methods for data collection, documentation, submission, review, verification, monitoring and archival should be explained in detail.

Statistics

This section should describe the statistical methods to be used in the trial to analyze the data. As the significance of the study trial is based on the statistical results, this section should be carefully designed. For writing these procedures a statistician should be involved. The number and name of variables used in the analytical calculations should be listed. For computerized statistical analysis methods, the name and versions of the software utilized should be mentioned. This section should also describe the statistical testing of data collected in on-going study, after completion of study and periodic review. This section should also explain and justify the statistical procedure to be followed for the deviations.

Procedure for Accounting for Unused and False Data:

This section gives knowledge about the procedure to follow to report any deviation from the pre-defined statistical plan and justification for it.

Follow-Up

This section should highlight the necessity of the follow up to the participants and for how much period of time follow up to be taken. The follow up are for any adverse events, any change in drug dose and frequency, missed dose etc. The follow up can be taken even after completion of collection of data for a specific study.

Strengths and limitations

This section should describe the benefits, advantages, limitations and disadvantages of the study. This section helps in proper resource allocation for the work.

Quality Control and Quality Assurance

This section should inform about the plan for controls and standards for confirmation of accuracy followed in each step. A protocol should provide a general description of methods for the quality control and assurance of the study.

Expected Outcomes of the Study

This section provides information about the effect and contribution of the study to the current knowledge. The utilization of research outcome for health benefits are mentioned in this section. It also helps information of new healthcare policies.

Ethics

The protocol should describe ethics and confidentiality of the study in relation to protection of participants. This section should mention the process of ethical approval and from whom it is to be taken. It should also address the issues which raise ethical concerns of the participants. This section should describe about the informed consent, plan and process to take consent from the participants. There should be freedom to the participants to withdraw from the study at any point of time as per their wish. The safety and secrecy for data should be maintained.

Informed Consent Forms

The informed consent form format must be there in approved protocol. The consent form have be approved by Ethical Review Committee (ERC).The consent form should be in two language i.e. English and local language. The consent form should explain the risk and benefits associated with the trial, justification of the research purpose with social and physical implications.

Budget

This section describes the finances and insurances of the study in detail. In some research protocols, it is documented in a separate agreement. This section should contain a detailed item-wise breakdown of the funds requested, with a justification for each. It should also consists of head wise funds received and expenditure in detail like for staff, instruments, laboratory tests, cost of the drug, transportation etc. The estimate of finance is to be attached in annexure. All costs including personnel, consumables, equipment, supplies, communication, and funds for patients and data processing are all included in the budget. Each item should be justified.

Publication Policy

This section provides the publication policies, guidelines and procedures of study findings publication in detail. The publication policy should be discussed regarding the leads and acknowledgements in the publication. Investigator should know and follow the publication requirements and policies from institution and sponsor. In accordance with the Food and Drug Administration (FDA) Amendments Act (42 CFR Part 11), clinical trial findings and results will also be published on a public website, ClinicalTrials.gov. Sometimes publication policy is documented in a separate agreement.

Project Management

This section should describe the role and responsibility of each person of the team involved in the study.

Conflict of Interest

Identify and document clearly; any consultative relationship that the principal investigator or co-investigators found unrelated to the protocol that might be considered a real or apparent conflict of interest.

Timeline

This section should give the timelines of starting and completion the study. The protocol should specify the time for each phase of the project. The proper time table for accomplishing each activity of the study should be defined. The protocol should specify the time along with a detailed month by month timeline for each activity. Assigning time frame to each step in the trial will be helpful in organizing the structure of the research trial. The adherence to the time schedule will allow study completion on time.

References

Plagiarism is copying other's research and considered as a crime. Plagiarism is failure to referencing and acknowledgement to other researcher's work. So, referencing is an extremely important aspect of the research protocol.

Referencing is the recognizing the information taken from the other research work. A citation for the background information will be useful for the readers to take reference for an interested area. All references should be listed at the end of the protocol. The reference formatting depends upon the funding agencies to where submission of protocol will be done. In clinical writing, the most commonly used citation systems are the Vancouver and the Harvard system. **Annexure**

The annexes are need to be attached at the end of the protocol:

1. Informed consent form.
2. Letters from ethics committees.
3. Study questionnaire (copies of any questionnaires or draft questionnaires).
4. Case Record Forms (CRFs).
5. Budget details.
6. Curriculum Vitae (CV) of the chief investigator and co-investigator and their role in the study.

Supplements

Any additional information regarding research is provided in this section. The templates of informed consent, forms, manuals, handbooks are attached in this section.

GOOD PROTOCOL

Good protocol ensures well-defined role of every personnel involved in study. Study should yield the expected outcome of research. The protocol should answer the research questions adequately. The protocol should give detailed methodology, which can be guidance document for another investigator also. (Al-JunDi, and Sakka, 2016)

There are some common mistakes to avoid during writing of protocol. Insufficient parameters, inadequate explanation, sample size, excess of work in less time period, practical applicability of the procedures, unreliable instrumentation, improper statistics are need to take into considerations and analyzed. (Eaton and Santini, 2007).

As research protocols are lengthy, there might be chances of human errors. Use of some tools for any spelling mistakes and grammatical mistakes can be carried out to avoid it. The protocol can be checked by using automatic software, peer reviewing and proofreading to avoid mistakes. (O'Brien and Wright, 2002)

The templates of clinical research protocols are available for guidance and reference. The template varies depending on the phase of clinical trial, type of design of study like intervention studies, descriptive, observational and registry studies. The protocol writing guidelines and templates are freely available on <https://clinicaltrials.gov>, <https://grants.nih.gov/grants/oer.htm>, https://hub.ucsf.edu/protocol-developmentandhttps://www.who.int/rpc/research_ethics/format_rp/en/ etc.

PROTOCOL REVIEW

After finishing complete write-up of the protocol, it should be reviewed and approved by the experts. The approval and monitoring of clinical trial must be done by an Institutional Review Board (IRB). This is an independent committee which includes healthcare professionals like physicians, dentists for review of scientific information, statisticians for data analysis and members of the society as a common man. The committee ensures the safety of the participants and ethics of the study with the protection of participants. After protocol approval the IRB should review the study periodically. The review ensures that the protocol has minimum risk with more potential health benefits to the participants. (O'Brien and Wright, 2002 ;Hulley, et. al. 2001)

PROTOCOL CLARIFICATION

A protocol clarification helps into the implementation and conduct for the research study. It clarifies no any change in protocol. It also gives internal guidance. There is no need of submission of clarification to IRB. It should be provided in writing to all investigators. (Al-JunDi and Sakka, 2016)

PROTOCOL VIOLATION

A protocol violation also referred as protocol “deviations.” It occurs when a staff performs any action that does not adhere to the research protocol. It may be an omission, addition or change in described procedure. The violation of protocol is a human error and may be because of a problem with study oversight, training to personnel, or study procedures. The study personnel should take efforts to stick to the protocol and not to make violations. If it occurs, then corrective action should be taken, written, notified and submitted to the IRB. The violations must be informed and reported to the study investigator, sponsor and regulatory authorities if required. If violations are repetitive by the staff, there is need of training or a protocol amendment depending upon the type of violations. (O’Brien and Wright, 2002; Al-JunDi and Sakka, 2016).

PROTOCOL AMENDMENT

If there is need to update the research protocol, then the changes should be described in detail in written document. Before implementation, the amendments should be submitted in written to the Institutional Review Board for review and approval. But if the changes are administrative type or immediate removal of any hazards to participants then there is no need of prior approval from IRB. The amendments are need to submit to the sponsor. If the study involves a product regulated by any specific regulatory authority, the amendment must be submitted to the same and also to IRB before implementation. After approval of protocol amendment, all the research participants must be informed about the changes. If required, the informed consent should be also revised and signed by the participants as per the changes. (Al-JunDi and Sakka, 2016; Hulley, et. al. 2001, O’Brien and Wright, 2002).

FUTURE RESEARCH DIRECTIONS

A good protocol can be a reference guide for other clinical trial investigators. The protocol development in clinical trial should be more focused and carefully written. This document will be providing a self explanatory detailed guideline for various elements and procedures to be followed during the clinical trial study. Also the justification of all the processes, sample size selection, lab tests, statistical analysis etc should be provided in the protocol. The protocol should include all instructions, clarifications and related examples in it. There is more need to pay attention to include all data related to preclinical and clinical study in protocol. So that the protocol should be answer all the questions.

CONCLUSION

Clinical research is a systematic investigation for treating the diseased conditions, overall health improvement and longevity of human. Clinical trials follow a pre-designed study plan for health-related research studies in human. This plan is called as ‘research protocol’ and is very important aspect in conducting clinical trial. To perform clinical trial properly understanding of the steps involved in the trial is essential. For better and sequential understanding of clinical trial process, methodologies and for the reliable data collection, a good protocol should be written. Protocol writing is a collaborative effort by a team

which makes sure that the scientific procedures are practically applicable. It should be accurate, clear, comprehensive, without errors and easy to understand. It should summarize all the details of the research trial. The protocol writing is lengthy and time consuming process. But the time spent to write a good protocol is worth as it saves the time and failures coming in actual conducting a clinical trial later on. Good clinical trial opens up new therapeutic options for a specific disease. The good study determines the safety and efficacy of the new treatments and helps in overall improvement of human health.

KEY TERMS AND DEFINITIONS

Clinical Research: This research is carried out to ascertain the safety, efficacy and effectiveness of the new drug product or new therapy for treatment of a specific disease in human.

Clinical Trial: This research is experiments carried out in human, observations are recorded to determine the safety and efficacy of the therapy.

Investigator: The individuals who actually carry out and monitor the clinical trial.

Pre-Clinical Study: This is part of clinical research in which the safety of the new drug or treatment is carried out on experimental animals.

Protocol Deviations: The non-compliance to the protocol is protocol deviations but this does not significantly affect the risks and benefits of the clinical trial.

Sponsor: The sponsor can be a person or organization which provides all financial assistance to carry out a clinical trial.

Study Protocol: This document provides details of each step to be carried out in clinical research.

A Regulatory and Safety Perspective on Medical Devices

INTRODUCTION

In Europe, medical devices market account for sales of EUR 100 billion, with the medical devices industry employing 575,000 people in the European Union (EU). This industry is one of the most representative employers in this economic area (European Commission, 2018). In 2015, the United States medical device market was evaluated at more than \$140 billion, which represented nearly 45% of the global market (International Trade Administration, 2016). By 2021, the market of medical devices is expected to globally attain \$342.9 billion, mainly due to the ageing of population (Lucintel, 2016). The main commercial trends in medical devices are, as follows: surgical and infection control, general medical devices, cardiovascular, and home healthcare. It is expected that in the future medical devices will tend to be smaller, portable, and including software (Lucintel, 2016).

The design and marketing of medical devices is strictly legislated. In accordance with World Health Organization (WHO) and Global Harmonization Task Force a medical device is defined as:

“an article, instrument, apparatus or machine that is used in the prevention, diagnosis or treatment of illness or disease, or for detecting, measuring, restoring, correcting or modifying the structure or function of the body for some health purpose. Typically, the purpose of a medical device is not achieved by pharmacological, immunological or metabolic means” (WHO, 2018; Global Harmonization Task Force, 2012).

Additionally, the Food and Drug Administration (FDA) through the 201(h) of the Federal Food Drug & Cosmetic (FD&C) Act defines a device as:

“an instrument, apparatus, implement, machine, contrivance, implant, in vitro reagent, or other similar or related article, including a component part, or accessory which is: recognized in the official National Formulary, or the United States Pharmacopoeia, or any supplement to them, intended for use in the diagnosis of disease or other conditions, or in the cure, mitigation, treatment, or prevention of disease, in man or other animals, or intended to affect the structure or any function of the body of man or other animals, and which does not achieve its primary intended purposes through chemical action within or on the body of man or other animals and which does not achieve its primary intended purposes through chemical action within or on the body of man or other animals and which is not dependent upon being metabolized for the achievement of its primary intended purposes” (FDA, 2018a, 2018b).

DOI: 10.4018/978-1-7998-3479-3.ch125

Particularly, medical devices are regulated in accordance to Council Directive 93/42/EEC in the EU. According this Directive, all *medical devices must be designed and manufactured in such a way, that, when used under the conditions and for the purposed intended, they will not compromise the clinical condition or the safety of patients, or the safety and health of users or, where applicable, other persons, provided that any risks which may be associated with their use constitute acceptable risks when weighed against the benefits to the patient and are compatible with a high level of protection of health and safety.* In addition, each member state of the EU has a National Competent Authority (NCA), which oversees specific designated Notified Bodies (NBs), i.e. the private entities, which are responsible for the certification of medical devices and for compliance of medical devices to EU Directives (Kramer et al., 2013; World Bank income group, 2016). NBs are responsible for evaluating the risk analysis and risk management strategy of the manufacturer (article 26 of Decree- Law No. 145/2016). In Portugal, the NCA - INFARMED, I.P. - is responsible for designating and supervising the national NBs (article 22° and 25° of Decree- Law No. 145/2016,) or for supervising the marketed medical devices (article 60° of Decree- Law No. 145/2016).

All incidents regarding medical devices (e.g. malfunction, deterioration, or performance issues) are recorded and centrally evaluated by the competent authorities of each member state (article 10 of Council Directive 93/42/EEC); if the alerts on MDs are considered relevant (e.g. potential adverse events related to medical devices), they are circulated between member states in the form of a National Competent Authority Report (NCAR) (EU statistics, 2017). Among others competences, NCAs are responsible for communicating adverse events with medical devices to the European Databank on Medical Devices (EUDAMED) (Kramer et al., 2013). EUDAMED aims at the collection of information, the exchanging of information, and conduction of marketing surveillance on medical devices in all member states (European Commission, 2001). Similarly, FDA is the authority responsible for regulating manufacturing and marketing of medical devices, since 1976. A premarket approval is usually required for higher-risk devices. The applications of these devices usually comprise clinical data and must include data to prove safety and efficacy (FDA, 2018a; Jarow & Baxley JH, 2015; Peña, et al, 2007).

Despite these strict regulations, every year safety issues involving medical devices arise. For instance, in a cohort study (2005-2010) specifically enrolling cardiovascular, orthopedic, and neurologic devices first approved in the EU, safety issues and reporting of trial outcomes were quantified in comparison with the outcomes of the approved medical devices in the United States (US). This study concluded that devices first approved in the EU were associated with an increased risk of post-marketing safety alerts: 27% (62/232) vs. 14% (11/77), respectively, for safety alerts and recalls for devices approved first in EU vs. US (unadjusted rate); 2.9 (95% confidence interval 1.4 to 6.2) for the adjusted hazard ratio (Hwang et al., 2016). Contrary to this conclusion, another study identified a small difference between absolute occurrences of serious medical device recalls between the US and EU. Considering that EU approves a higher number of medical devices than US, the proportional number of serious occurrences with these products may be even lower in the EU (Davis et al., 2011). An in-depth analysis of clinical safety and effectiveness used in health technology assessments of high-risk medical devices was conducted in Europe through the evaluation of reports published between 2010 and 2015. It concluded that the quality of scientific evidence (e.g. scientific data) is low, thus recommending the application of higher quality standards such as the obligatory implementation of methodologically robust trials (associated with other evidence sources) (Olberg, B., Fuchs, S., Panteli, D., Perleth, M., Busse, R., 2017).

BACKGROUND

The core study focus was the description and analysis of all Portuguese national safety alerts on medical devices during 2017, since these were the most recent data available at the time of this analysis.

A review of the Cochrane Library¹ using the key-words “medical device” and “alert” was performed and only four results, not related with regulatory issues, were identified. This fact confirms the need to undertake this analysis and understand deeper the potential risks associated with the use of these health products.

In this sense, it was also considered necessary to present the current classification of medical devices specifically in EU, including Portugal, as well as, to present examples of devices per their classification to enhance the intelligibility and comprehensibility of this study. Thus, study objectives were summarized, as follows:

- To present the definition and classification of medical devices in EU,
- To give some examples of medical devices per classificatory group, and
- To describe and analyze all Portuguese national safety alerts on medical devices in 2017.

METHODS

In this section, methods are presented per each one of the defined objectives.

Definition and Classification of Medical Devices in EU, Including Portugal

Definitions/classifications were extracted from the national and international guidelines, namely Portuguese Decree Law No, 145/2009 and Council Directive 93/42/EEC. In addition, the new EU Directive 2017/745 on medical devices was taking into account, although not yet transposed to the Portuguese legislation.

Examples of Medical Devices per Classificatory Group

Examples of devices per classificatory groups were extracted and translated from the official website of INFARMED, I.P., since they are validated by each of the national medicines agency, which works in collaboration with the European Medicine Agency (EMA) and other international medicine agencies such as FDA (INFARMED I.P., 2016). On the other hand, it was considered that many readers are not familiar with types/examples of medical devices.

Portuguese National Safety Alerts on Medical Devices in 2017

National safety alerts on medical devices were collected from the official website of INFARMED, I.P.² All Portuguese national safety alerts on medical devices were briefly described and analyzed for the year 2017. The qualitatively and quantitatively analysis was performed by two independent researchers.

The quantitative analysis was mostly descriptive (number and percentage of medical devices by classes).

The qualitative variables were conveniently defined based on the published text of the safety alerts, as follows: devices with (or without) identified records of commercialization at national level; devices

voluntarily withdrawal from the market; and the remaining situations were classified in the group of “other”. Finally, the types of regulatory actions taken by the national medicine agency were identified.

RESULTS

Definition and Classification of Medical Devices in EU

The concept of a medical device is not uniform in all countries of EU. In Portugal, the following definition should be considered:

a medical device means any instrument, apparatus, appliance, software, material or article used alone or in combination, including the software intended by its manufacturer to be used specifically for diagnostic or therapeutic purposes and necessary for the proper functioning of the medical device, whose main effect intended in the human body is not achieved by pharmacological, immunological or metabolic means, although its function may be supported by these means intended by the manufacturer to be used in humans to purposes: i) diagnosis, prevention, monitoring, treatment or alleviation of disease; ii) diagnosis, monitoring, treatment, mitigation or compensation for an injury or a defect; iii) study, replacement or modification of the anatomy or of a process physiological; iv) control of conception (article 3, Portuguese Decree Law No, 145/2009).

The Portuguese concept is aligned with definitions of Article 1, Council Directive 93/42/EEC, since Portugal is a member state of the EU, i.e. member states of EU are aligned concerning the definition of a medical device.

Classification of Medical Devices According to EU Regulation

Medical devices are classified in the following categories: Classes I, IIa, IIb, and III in the EU. This classification is based on rules 1 to 18 of Annex IX of Council Directive 93/42/EEC, as follows:

- **Class I** (rules 1, 2, 4-6, and 12): either does not touch patient or contact only intact skin (only the ones that are not included in any of the other classes) (rule 1); channeling or storing for eventual administration (only the ones that are not included in Class IIa) (rule 2); come into contact with injured skin; used for mechanical barrier, compression, absorb exudates (only the ones that are not included in Class IIa) (rule 4); invasive in body orifice or stoma not surgically, transient use or short term use - if only in oral cavity, in ear canal or in nasal cavity (rule 5); surgically invasive, transient use - reusable surgical instrument (rule 6) and all other active devices (not covered in other classes) (rule 12);
- **Class IIa** (rules 2-5, 8-11, 15, and 16): channeling or storing for eventual administration, for use with blood, other body fluids, organs, tissues or may be connected to an active medical device in Class IIa or higher (rule 2); modify biological or chemical composition of blood, body liquids, other liquids intended for infusion - only filtration, centrifugation or exchange of gas or heat (rule 3); come into contact with injured skin, used for mechanical barrier, compression, absorb exudates - intended to manage micro-environment of wound + others (rule 4); invasive in body orifice or

stoma, not surgically, short term use or long term use - if only in oral cavity, in ear canal or in nasal cavity and not liable to be absorbed by the mucous membrane or connected to an active medical device in Class IIa or higher (rule 5); surgically invasive long-term use and implantable devices - to be placed in teeth (rule 8); active therapeutic devices intended to administer or exchange energy (only the ones that are not included in Class IIb) (rule 9); active device for diagnosis, if intended to supply energy, to image *in vivo* distribution of radiopharmaceuticals, or for direct diagnosis or monitoring of vital physiological processes (only the ones that are not included in Class IIb) (rule 10); active devices to administer or remove medicines and other substance to or from the body (only the ones that are not included in Class IIb) (rule 11); specifically to be used for disinfecting medical devices (only the ones that are not included in Class IIb) (rule 15); and devices intended for recording of X-ray diagnostic images (rule 16);

- **Class IIb** (rules 3-7, 9-11, 14, 15, and 18): modify biological or chemical composition of blood, body liquids, other liquids intended for infusion (rule 3); come into contact with injured skin, used for mechanical barrier, compression, absorb exudates - intended for wounds which breach dermis and heal only by secondary intent (rule 4); invasive in body orifice or stoma, not surgically, long term use (rule 5); surgically invasive, transient use, - biological effect, mainly or wholly absorbed or - intended to administer medicines in a potentially hazardous manner (rule 6), surgically invasive short term use, - supply energy/ionizing radiation or - undergo chemical change in body - or administer medicines - not in teeth (rule 7); active therapeutic devices intended to administer or exchange energy, - administer or exchange energy in potentially hazardous way or - intended to control or monitor or influence directly the performance of a Class IIb active therapeutic device (rule 9); active device for diagnosis, if intended to supply energy, to image *in vivo* distribution of radiopharmaceuticals, or for direct diagnosis or monitoring of vital physiological processes, - specifically intended to monitor vital physiological parameters where variations could result in immediate danger, or - all devices emitting ionizing radiation and intended for diagnostic and therapeutic interventional radiology (rule 10); active devices to administer or remove medicines and other substances to or from the body - if this is in a potentially hazardous way (rule 11), devices used for contraception or prevention of sexually transmitted diseases (only the ones that are not included in Class III) (rule 14); specifically to be used for disinfecting medical devices, - specifically to be used for disinfecting, cleaning, rinsing or hydrating contact lenses, or - specifically to be used for disinfecting invasive devices (rule 15), and blood bags (rule 18).
- **Class III** (rules 6, 7, 8, 13, 14, and 17): surgically invasive, transient use - specifically to control/diagnose/monitor/correct a defect of heart or central circulatory system through direct contact, or - for use in direct contact with central nervous system (rule 6); surgically invasive, short term use, - for use in direct contact with central nervous system, - specifically to monitor/control/diagnose/correct defect of heart or central circulatory system - by direct contact, or - biological effect or mainly absorbed (rule 7); surgically invasive long term use and implantable device, - used in direct contact with heart or central circulatory/nervous system, - biological effect or mainly absorbed, - undergo chemical change in body - or administer medicines (nor in teeth), or - specific derogation: breast implants and hip knee and shoulder joint replacements (rule 8); devices incorporating integral medicinal substances liable to act in ancillary way on human body (rule 13), devices used for contraception or prevention of sexually transmitted diseases, - if implantable or long term invasive (rule 14); and devices utilizing non-viable animal tissues or derivatives, not device in contact only with intact skin (rule 17).

Currently, a new Directive on medical devices (Directive 2017/745) has become into force in EU, but it only will be transposed (i.e. legally adopted) by each one of EU countries in the next years and medical devices already certified can stay on the market during the next five years (European Parliament and of the Council, 2017). After 2020 all medical devices will be certified in accordance the new Directive 2017/745, which is stricter than the current one (e.g. probiotics will no longer be available as medical devices, and many substances currently market as medical devices may be classified as dietary supplements) (Gruenwald, 2017).

Market Surveillance vs. Classification

Market surveillance on medical devices is supported by Directives 90/385/EEC (active implantable medical devices), 93/42/EEC (medical devices), and 98/79/EC (*in vitro* diagnostic medical devices). The criteria, such as the potential inherent risks in the use of the device; the possible incidents related to the characteristics and/or operation of the device; the duration of the contact of the device with the human body; or the anatomy affected by using the device, along the above mentioned classifications allow for classification regarding the type and risk, as follows:

- Low risk devices (Class I);
- Medium risk devices (Classes IIa and IIb; being the Class IIa low average risk and Class IIb high average risk);
- High risk devices (Class III) (INFARMED I.P., 2016).

Low risk devices (Class I) are only required to “*self-declare*” that they conform with the *Essential Requirements to the national Competent Authority in their country of origin*. Clinical and/or nonclinical evidence is needed to support approval of medium and high-risk devices (Classes IIa, IIb, and III) (Gail & Norman, 2016). Details on the definitions/classification of medical devices (Classes I to III) may be consulted in the background section.

Examples of Medical Devices per Classificatory Group

Some examples of medical devices by class are presented in Table 1 (INFARMED, I.P., 2016):

Overall, 32 safety alerts on medical devices were identified in Portugal during the year of 2017: 6 (18.8%) were related to devices voluntarily withdrawn from the market (e.g. counterfeit or falsified devices that were recalled from the market), 7 (21.9%) were related to other situations, and 19 (59.4%) were related to medical devices without identified records of commercialization at the national level (e.g. alerts disseminated by NCAs from United Kingdom, Denmark, and Poland) (Figure 1).

Most predominant actions taken by INFARMED, I.P. (NCA)

- For inexistent records or voluntary withdrawals of medical devices: the medical devices must not be used, sold, or distributed;
- For voluntary withdrawals or falsified medical devices: all devices must be returned to the manufacturer, and suspected adverse events should be reported to INFARMED, I.P.;
- For other situations: need to contact the distributor to obtain safety advice, update the software, or receive new instructions for use.

Table 1. Examples of medical devices per classification (INFARMED I.P., 2016)

Class	Examples	
Class I	Devices for collection of body fluids	bags of urine collectors ostomy bags diapers incontinence pads
	Devices intended to immobilize parts of the body and/or apply force or compression	cervical collars compression stockings elastic stockings knee braces for medical purposes
	Devices used for external support of the patient	walking aids wheelchairs hospital beds
	Non-invasive devices	stethoscope corrective glasses glass frames
	Devices intended for temporary content or with storage function	syringes without needle tablespoons specifically intended for administration of medicines
	Invasive devices with respect to body orifices for intended for temporary use	examination gloves
	Invasive devices used in the oral cavity as far as the pharynx, in the ear canal up to the ear drum, or in the nasal cavity Non-invasive devices that contact injured skin and are used as a mechanical barrier, for compression or absorption of exudates	Dressing material for nosebleeds solutions for irrigation or mechanical cleaning cotton wool bandages
Class IIa	Devices that are intended to manage the micro-environment of a wound	hydrophilic gauze, sterile or non-sterile occlusive adhesives for topical use
	Invasive devices with respect to body orifices, for use in the short term	urinary catheters vaginal pessaries
	Active devices with a measuring function	thermometer with battery or other associated source of energy
	Invasive devices with respect to body orifices, which are intended to be connected to an active medical device	heat and moisture exchangers
	Invasive devices for surgical nature, intended for temporary use	Needles syringes lancets surgical gloves
	Devices intended specifically to be used for the disinfection of medical devices	
	Devices that are intended to be used primarily in wounds that have breached the dermis substantially and extensively, and where the healing process can only be achieved by secondary intervention	dressing material for extensive and chronic ulcerated wounds
Class IIb	Devices that are intended for administration of medications	insulin pens
	Devices used for contraception and/or prevention of sexually transmitted diseases	male condoms diaphragms
	Devices intended specifically to be used for disinfecting, cleaning, washing, or hydration of contact lenses	Solutions of comfort for patients with contact lenses
	Devices incorporating a medicinal substance and constitute a single product that is not reusable and in which the action of the substance is ancillary to that of the device	condoms with spermicidal
	Devices used in contraception, invasive, implantable, or long-term use	intrauterine device, which does not release progestogens

Portuguese national safety alerts on medical devices in 2017

Figure 1. Type of public safety alerts on medical devices in Portugal (2017)

DISCUSSION

Brief Analyzes

Overall, there were few alerts on medical devices released and published in the official website of the Portuguese medicine agency during 2017 (i.e. only thirty-two alerts). This limited number of alerts may be associated with a limited number of marketed devices in Portugal, considering that the Portuguese economy have recently faced restrictions, but further studies are required to support this assumption. More than a half of alerts were on medical devices without identified records of commercialization in the Portuguese territory, since EU is an open marketed where goods, persons and services can circulate for free (EU, 2019).

Notified adverse incidents with medical devices are evaluated and, if relevant (e.g. severe incidents), they are circulated in the form of a NCAR. Only 0.3% of all NCAR were reported in Portugal. This finding is consistent with the limited number of alerts on medical devices identified at a national level (EU statistics, 2017). In 2017, the three most prevalent occurrences from the 981 (100%) NCAR exchanged between 17 EU countries were: 363 (37.0%), 190 (19.3%), and 115 (11.7%) in Germany, United Kingdom, and France, respectively (EU statistics, 2017). Thus, it seems that medical devices are safely used within the Portuguese market, although the extent of information available in the safety alerts of medical devices seems to be limited. For instance, the possible patients' safety consequences were not specifically described in the medical device alerts.

The types of instructions/actions taken by the competent authorities were variable depending on the type of alert. For instance, as expected counterfeit devices were withdrawn from the market. New actions/safety measures may be required by competent authorities to avoid the commercialization of these counterfeit devices even in EU, which is an extremely regulated market. Marketing surveillance of medical devices is fundamental to assure patient safety. In this sense, alerts to not purchase or use medical devices without identified records of commercialization are relevant, since within the European economic area, goods and people are free to circulate/move.

Solutions and Recommendations

The traceability of medical devices is a relevant issue, since people and goods move across borders (European Union, 2019). Therefore, it could be advisable that retail sellers of medical devices, such as ambulatory or hospital pharmacies, could collect patient data upon acquisition of the medical device and, if necessary, be responsible for warning the patient in case of new information or safety concerns related to the dispensed medical device. More public information on how to report adverse events in medical devices and how to consult safety alerts for medical devices should be created and disseminated. For instance, a national campaign on the safety of medical devices could be an important instrument to highlight the need to report potential adverse reactions and to raise awareness of the safety issues involving these devices. Furthermore, in order to avoid the introduction of counterfeit medical devices in the market, more straightforward supervision may be required.

Future Research Directions

In the future, all medical devices (or their packages) may be associated with an electronic mechanism to allow traceability and the recognition of a medical device with related safety issues, as a way of emitting alerts. The development of economic, safe, and efficient medical devices is relevant to assure patients access to these health products. New classifications and regulations on medical devices may be required if new classes of medical devices appear. Citizens and patients may be questioned on the usability and intelligibility of medical devices. In EU, including in Portugal the impact of the application of the new Directive 2017/745 should be monitored, to allow the analysis of a possible better risk-benefit profile of the new approved medical devices through the application of the new Directive. Also, comparative studies of clinical safety on approved medical devices (e.g. between EUA e UE) should be carried out to support the robustness of the methodology used in high-risk trials to approve medical devices.

Finally, it will have a major impact the development of a longitudinal study comparing the number of alerts reported in Portugal with the data in another EU countries and the total number of alerts reported in the EU for medical devices.

CONCLUSION

In 2017, a small number of safety alerts on medical devices were identified in Portugal. A significant part of these alerts were related to devices not market in Portugal, which may have contributed to this low number of alerts. The types of instructions/actions taken by the competent authorities depended on the level of risk associated with the use of a certain device. As expected, the most serious events (or potentially serious events) were associated with withdrawals of devices from the market, such as in the case of falsified devices. Although the number of identified counterfeit devices was very limited, this situation represents a potential public health risk/concern.

KEY TERMS AND DEFINITIONS

Competent Authority: A public authority with specific competences in the commercialization medical devices.

Class I-III: The classes/classifications of medical devices in accordance to Annex of the IX, Council Directive 93/42/EEC.

Directive: A regulation/law in European Union.

EUDAMED: A European database comprising commercial and safety information on medical devices.

INFARMED, I.P.: The Portuguese medicine agency.

Medical Device: A device for medical use, which may not be classified as a medicine.

Notified Bodies: A private entity responsible for certifying medical devices in accordance to law.

Note: CBIOS - Universidade Lusófona's Research Center for Biosciences and Health Technologies, Campo Grande, 376, 1749-024, Lisboa, Portugal.

INTRODUCTION

Pandemic crisis, location of the primary case and individual medical data are all major concerns and features in the global health environment. Pandemic crisis, *i.e.*, an epidemiological outbreak that is simultaneously on several continents, with all the social, economic and individual mayhem it provokes, links tightly with the location of the primary case, which is the individual who introduces the disease into the population, and whose clinical data, *i.e.*, the genetic and personal health related data, may prove invaluable to assess the global health policies and countermeasures on the crisis.

These three aspects are among some of the Health and Social problems that the emerging medical social networks can positively address. Medical networks, which work as an interface between the patient medical data and his/hers geographical and/or social connections, as well as between the patient's individual needs and the attending medical doctor, can allow feasible and fast visualization/information systems. Furthermore, they are effective and emerging research tools in studying health policies and detecting how to improve them.

In the recent five years, there has been an increased research interest in the development and application of informal medical social networks, as well as data concerning the real advantages of their use on daily situations and Health Policies Implementation. In 2018, an ideal model for a medical social network and data visualization information system has been proposed (Gonçalves, Moura, Cordeiro & Campos, 2018), which considers both the individual and the socio-economic needs and rights, and it is likely that the first prototypes can be presented in the near future.

This chapter reviews the evolution and *status quo* of prospective medical social networks, and discusses the ideal model and its future venues and interaction with ethics in the areas of Economics, Health Policies and Human Rights.

BACKGROUND

The advent of the concept ‘medical social network’ came in 2007, when Barabási published a work entitled *Medicine Network: From Obesity to the “Diseasome”* (Barabási, 2007). Though Barabási used the term ‘medicine network’ instead of ‘medical social network’, he defended that since networks can be found on every particulars and features of human health, as knowledge regarding its effects on the patients’ biomedical aspects increased, a new field of expertise on medical practice and research would appear. These medical social networks were constructed and studied through graph theory visualization, namely as nodes and edges (Newman, 2010).

A node, within a social network, is defined as a distinct entity, which can be single, like a person or a molecule, or collective, like a country or a company. An edge, in the same context, represents the connection between two different nodes. The connections are multi-natured, *i.e.*, they can be friendship or working connections, for example, if one thinks of human individuals; but they can also be of chemical definition, for example, as the bond type between intramolecular atoms. Exemplifying, when restricting to the medical context, the nodes may represent people, coupled by their biological or psychological factors, such as obesity (Christakis & Fowler, 2009) or depression (Rosenquist, Fowler, & Christakis, 2011), but they can also represent diseases themselves, like in comorbidity studies, *i.e.*, the causal interaction between diseases (Folino, Pizzuti & Ventura, 2010). In the same context, the edges are the type of connections between the people, *i.e.*, genetic/familiar or geographical, or different causal levels of comorbidity, if the nodes are diseases. These simple examples do not exempt the graph model to have added complexity, since the nodes can also comprise the information of gender, for instance, apart from the genetic or otherwise bio, social, or psychological factors. Figure 1 illustrates in a simplified manner the relation between real interactions and corresponding graphs.

Figure 1. Example of a multi-layer social network representing real life connections between people. (Image obtained with software MuxViz(De Domenico, Porter & Arenas, 2015).)

Figure 1 represents a social network with two layers. The left, or first, layer represents the kinship between the nodes, which are individuals, and the right, or second, layer represents cohabitation connections. The pink nodes represent female individuals and the blue nodes represent males. The size of the nodes is proportional to the age of the individual, and in the left layer, the edge colour represents different kinds of family connections. Yellow stands for grandparent/grandchild connection, green stands for

parent/offspring ties, and, in red, one has sibling relationships. As the right layer stands for one type of connection only, *i.e.*, cohabitation, all edges have the same colour. This is a type of social network that adapted for medical purposes could allow for contagion detection in several types of diseases, identifying those from direct contact or genetic/hereditary.

Indeed, almost fifty years ago, the importance of meeting health information with global population knowledge had already been signalled as fundamental for developing public health policies and sound implementation near the populations (Wennberg & Gittelsohn, 1973). Decades later, when the Internet was already becoming established as a worldwide means of information for the global population, with the increasing popularity of instant messaging programs, such as the extinct AOL Instant Messaging (AIM), again this idea was reinforced, by researchers, stating that such a type of synergetic information system could aid both national and regional health policies, by monitoring efficient allocation of medical resources, either human or logistic, and adapting those medical resources to the citizens' different idiosyncrasies, from health status to socioeconomic risk, and access to the several medical resources (Roos *et al.*, 1999).

The past fifteen years witnessed the emergence of several models of medical social networks for applications ranging from analysis of public health policies to locating patient zeros on epidemic crisis, and even studying contagion on conditions such as depression or obesity. The present state of application and use of these models, as well as their theoretic and practical principles, are discussed on the following sections, per type of application, *i.e.* if they are applied in public health policies monitoring or analysis of disease contagion, for example.

FOCUS OF THE ARTICLE

Getting insight into the many areas of application and scope of utility of medical networks can be made more feasible by discriminating such areas into two major groups, one where the context is the human extension of the population composing the medical network, *i.e.*, the order of magnitude of the population, and the other context is the type of human quality being analysed, *i.e.*, the dependent variable, either quantitative or qualitative, under scrutiny. In the first case, one can broadly consider three main population magnitudes: global, national, and community wide. On the second context, one can also consider three main quality types: physical, mental/cognitive and social. All of these, whose connections are illustrated in Figure 2, are discussed in the following subsections in the form of relevant case studies.

With this classification as guidance, the selection of the literature to be discussed followed. Several criteria were applied on this selection: (a) only one publication *per* the above defined categories; (b) the chosen publication should be a clear example of the category, with the purpose of practical application and, ideally, with proven results; (c) in case of an equal situation for two publications regarding (a) and (b), the publication with the most relevance for the development and implementation of social medical networks, seen by citation and/or practical implementation, was chosen; and (d) the final criteria would be the most recent publication, if similar status was met by two publications within (a), (b) and (c) context. As such, six case studies, one *per* category, were selected and are discussed in the following subsections.

Medical Social Networks: Global Order of Magnitude

The use of social networks for medical purposes can also depart from plain social networks *per se*. In fact, online apps for social interaction, such as Facebook, Instagram or Twitter, represent an excellent

Figure 2. Areas of application of Medical Social Networks, according to the order of magnitude of the populations being addressed, and according to the type of health feature in study.

sample of global population as they have, respectively, 2.27 billion (Statista, 2018), 1 billion (Omnicores, 2018), and over 300 million (The Balance Careers, 2018) monthly active users. Given the various type of personal data that can be collected from such social networks it was inevitable that medical applications would resource to it. A recent and interesting research explored the eventual relation between the use of social media and personal well-being (Shakya & Christakis, 2017). The work departed from the premise that non-virtual interaction enhances personal well-being and explored if such a conclusion could also be reached for virtual active relationships. Within four domains of well-being, namely body mass index, self-reported life satisfaction, self-reported mental and physical health, the objective public data from Facebook users was cross referenced with three waves of self-reported measured social data from non-virtual social networks.

The researchers concluded that, within some significance variances, a rather robust pattern was identified. Real-life social networks are positively associated with overall well-being, while Facebook use is negatively associated. Nevertheless, they also point out that the negative associations with Facebook use were stronger than the positive associations of real-life interactions with overall well-being. They also asserted that the positive interaction with other Facebook users' content, *i.e.*, 'liking' posts or links of other users, was consistently related with a more compromised overall well-being, while the quantification of Facebook updates, *i.e.*, the number of status updates of each user, was associated with diminished mental health. Other aspects, such as greater number of Facebook friends, *i.e.*, the user's Facebook network, though evidencing positive association with well-being in cross-sectional models, lost its significance when within a longitudinal model. A hypothesis laid by the authors was also the

mutually exclusive nature of offline versus online relationships as the negative associations of Facebook and positive correlations of real-world interactions were of comparable extension.

The use of social networks data in medical social networks as an effective monitor of several aspects of well-being was demonstrated (Shakya & Christakis, 2017). However, it should be noted the following: other than public data Facebook users might provide, the interaction data is subject to permission and that affected the longitudinal data size, and the study was unable to identify the mechanism through which Facebook use causes reduced well-being. Though the second can be, and is being, explored in new studies, the first is of extreme importance. Data protection is becoming a more urgent matter, as scandals associated with the misuse of social networks ravel one after the other. Though the right for privacy is undisputed, the interface between such right and the medical access to private data collected through social network apps must be thoroughly defined and with optimal consequences for both parts. Such aspects will be addressed on the section of *Future Perspectives*.

Medical Social Networks: National Order of Magnitude

The potential of developing a health integrated system of information for medical practitioners and Public Health decision-makers alike had already been duly right before the turn of the century (Roos et al., 1999). This work, though not formally introducing data from social network apps into a medical social network, since at that time the online social media was still an Internet toddler, it proposes a synergetic network model that illustrates how present-day data can be integrated in a medical social network.

The authors departed from the traditional overall assumptions that coordinated the allocation of hospital services in national and regional scenarios, *i.e.*, population growth associated with health policy decisions of increasing or allocating new hospital services in the growth region or increased demand on volume of use. They also took into consideration that the care assessment focused the individual results of treated citizens or the rating of hospital institutions, and pointed out this was rooted on the conviction that across the overall populations, there was a similar need for specific health care.

However, many studies seemed to challenge these assumptions and in response they elaborated a model that proposed a comprehensive population health information system whose administrative database cross-referenced the following areas: location of allocated care (medical clinics, nursing home, hospital institution, citizen home), overall population statistics (including census), health-related services data (as from pharmaceutical services, for example), and physicians data. The model linked four sets of population information (population health, socioeconomic risks characteristics, health care expenditures, supply of health care resources) and would organize the information per geographical area according to these indicators. Another important feature of the model was how both policymakers and the general public would be able to discriminate factors within the health issues as independent social levers outside formal health care systems could be identified (Roos et al., 1999).

The authors conclude by stating that the capabilities of such an information system only now are being explored, and that the specific system they present creates a dynamic interface between academics, policymakers and the general public. In fact, at present, such benefits are becoming a reality with the inclusion of these types of data in prototypes of medical social networks.

Medical Social Network: Communal Order of Magnitude

The third case study within the extension variable regarding the applications of medical social networks, used an algorithmic method applied to such networks in order to evaluate how several Indian communities

changing a specific health habit, which was the ownership of a latrine, would not only affect both the community and village level of latrine ownership but also how the network cohesion affected individually the villagers in such matter (Shakya, Christakis, & Fowler, 2014).

The researchers explored both descriptive, *i.e.*, communal regular behaviour adopted without other's expectations, and injunctive, *i.e.*, communal standards enforced by social sanctions, norms within the context of individual latrine ownership *versus* community health habits change. They considered three social levels, friendship, social network community and overall village social network. It became clear that there was a strong association between owning an individual latrine and changes in all three levels, albeit the strongest effect was found at the social network community level. In fact, the higher the level of community network cohesion, the lower the probability of individual latrine ownership, though this only applied to the cases where the number of individual latrine ownership were less significant.

The authors concluded that health and international development interventions in such context should be determined not by geography but using social network knowledge, breaking traditional statistical data approach to a more humane and intelligible health policy.

Medical Social Networks: Physical Variables

This entry marks the first case study of medical social networks within the context of human quality types. Human health presents several aspects, and the most obvious since the early days of medicine was the physical aspect, *i.e.*, the overall aspects of the bodily parts and functions of a human being. This research studied how a prevention of a physical infirmity as a cardiovascular event and the adoption of preventive measures by social interactions could be associated (Strully et al., 2012). The authors considered the aspirin intake as the preventive measure and used a longitudinal logistic regression model to explore such scenario in three data waves extracted from the Framingham Heart Study. The study also included several individual aspects, such as gender or type of social connection, and approached the results through traditional statistical functions, displayed in tables.

The conclusions had two main aspects. Regarding the premise of the study, the sharing of medical doctor was a common feature when the aspirin intake habits were changed. The second aspect was the conclusion by the authors that such a traditional display of results made difficult to locate the individual aspects that sustained such changes. For example, and taking into consideration the identification of the common feature, *i.e.*, the sharing of doctor in individuals changing habits regarding aspirin intake as a preventive measure for cardio vascular events, it was not possible to determine if the doctor had actively influenced the decision. The authors themselves pointed out that the non-inclusion of a social network model could be the limiting factor in identifying such aspect, as well as others (Strully et al., 2012).

Medical Social Networks: Mental/Cognitive Variables

Depression, as other mental infirmities, had empirically been thought to be associated with social factors. However, the inclusion of social network models to conclude regarding health care in such context has only been studied in recent years, as in this case study, which had a sample of a more than ten thousand people social network (Rosenquist et al., 2011). Furthermore, the sample was assessed several times over a timespan of more than three decades, and longitudinal statistical models were used to probe how individual depressive symptoms were related with similar symptomatic levels of their social network. The personal connections would vary from the genetic liaison, as in siblings, for example, to intimate, as in spouses, to geographical, as in neighbours.

Correlation was found between depressive symptoms and intimacy and geographical connections, *i.e.*, proximity to the home of the depressed individual would affect the depressive levels of the others. Gender was also a variable to be considered as fulcrum, since being cumulatively a female within the proximity would seem more susceptible to be influenced. The results were robust through several simulations of the network and other methodologies and reveal the contagion features of depressive states (Rosenquist et al., 2011).

The authors stated that the inclusion of social network models for medical data would allow to not only better understand the impact of interpersonal relationships on mental conditions but also how to develop future health policies that could locate and prevent the conditions for contagion.

Medical Social Networks: Social Variables

The final of the selected case studies regards the social aspects of human health and human health policies. In this work, the question in wanting of answer was if health policies targeting the change of health habits, namely in nutrition, that focused in the public example of influential individuals were efficient. In order to obtain an answer to this question and being able to develop health policies that maximized the level of population behaviour change, the authors recruited individuals from thirty-two Honduran villages and discriminated the villages on network size, socioeconomic states, and baseline rates of water purification for two intended public health inversions, one regarding the use of chlorine in water purification, the other, regarding multivitamins intake for micronutrients deficiencies (Kim et al., 2015).

It was concluded that change in health habits was far more efficient through close personal connections rather than through the example of influential individuals. The intervention diffusion could be maximized by analysing the properties of the human social network. The authors clearly indicated that the adoption of social network models to health-related data could be a more sustainable and efficient manner to develop public health policies and interventions.

SOLUTIONS AND RECOMMENDATIONS

On a recent publication, an ideal model for the principles and day-to-day application of a medical social network was suggested (Gonçalves *et al.*, 2018). Through a story-type scenario, the model proposes the ideal interaction between a physician and a hypothetical patient, Mr. Silva. Mr Silva has a pre-scheduled appointment with his personal doctor, being it on a private or public medical institution is irrelevant for the model. Due to this pre-scheduling, the doctor can access all the data the patient has previously authorized to be available for the medical professionals dealing with his case. This data includes, for example, standard clinical data such as doctor appointments records, blood tests results, or X-ray images, but also social network data.

The specifics of social network data available to the doctor are: (a) relevant medical data for Mr. Silva's health status of kinship, *i.e.*, of the first degree relatives such as parents, siblings, or offspring, and second degree relatives, such as uncles, aunts, grandparents or full cousins; and (b) relevant public alert on medical networks, either national or local, affecting Mr. Silva's (i) working relations and (ii) neighbourhood interactions. This would allow to cross-reference the patient's personal medical records with family medical history and social interactions. As such, the physician is not only up to date with much (though not all) of the needed information to support the diagnosis of Mr. Silva, even prior to his entering in the room, but is also in a position to act as a public health agent for disease prevention on

a local and national scale. Further, and reinforcing the authorization Mr. Silva must give for the availability of the above-mentioned data, the right to privacy is guaranteed as the doctor only has access to the type of relationships and respective clinical data but never to the identity of the individuals of Mr. Silva's social networks (Gonçalves *et al.*, 2018). On an eventual public health crisis, the identity of the connections could be revealed, after external authorization, taking in consideration all present legal and human rights regarding privacy.

The public interest and purpose of the ideal model would be sustained by the continuous synergetic work of professionals from areas such as data management and analysis, information technology (IT) analysis and health practitioners which would cross-reference an array of medical social networks with the detection of potential health threats. These threats could be either of sporadic situations, such as epidemics, or ongoing, such as depression (Rosenquist *et al.*, 2011).

An interesting recommendation for upgrading this model would be to have the type of data regarding Mr. Silva's kinship elaborated for the adjacent geographical connections, established by a pre-defined radius for circular areas around his home and/or workplace. Further, the model should be accompanied by the implementation of mandatory instructions for medical professionals in order to be understood not only how it works but also what data is still needed to extract from the patient, *i.e.*, it should be clear that the ideal model is not a diagnosis system but a supporting system for the diagnosis.

The aspect of privacy within the social medical networks can be considered a research field on its own, and more so with the new pivotal role of artificial intelligence (AI) on IT. AI implies that algorithms, *i.e.*, the specific process on a given computer operation, can be developed to emulate human performance on tasks such as decision-making, and if one adds that to the emergent AI field of machine learning, which allows the computer systems to automatically improve through the identification of problems and auto-correction, the concerns regarding the misuse of personal and medical data available on medical social networks are real and need to be seriously addressed.

As such, and collecting from public and governmental documents, as the 'Guidelines on Artificial Intelligence and Data Protection' of the Council of Europe, one can identify the following main aspects that need to be incorporated in the ideal model (Convention 108, 2019): (a) according to the principles of Convention 108+, the ideal software model should incorporate privacy-by-design and by default, while taking into account the proportionality of data processing and the purpose specification, and policy makers should impose on AI developers, manufacturers, and service providers the mandatory need to assess the impact of data processing of the developed software on fundamental freedoms and rights, namely the right to privacy, before the product implementation (Council of Europe, 2018); (b) the risk assessment of these softwares should adopt a multiview of possible outcomes of the data processing, in order to be aligned with human rights, fundamental freedoms and the functioning of democracies and social and ethical values – this aspect is particularly important in the development of an ideal model of a medical social network, as the application presupposes scenarios where the greater good versus individual freedom may be present, as in the case of epidemics (Council of Europe, 2017); (c) as all human interactions provide and are recipient of meaningful transitions, from a cognitive and emotional perspective, these AI medical applications should allow the data subjects, *i.e.*, the human subjects, to interact with the data processing and its effects with meaning, that is, the process should not be developed in such a manner that it increases the hypothetical software illiteracy of the subjects; and (d) the subject's right to intervene on the AI decisions should be preserved, and the AI developers, manufacturers, and service providers should be responsible and accounted for adopting an algorithm vigilance which assures the applications respect the data protection principles and human rights.

A final recommendation, and taking into consideration that the contextual nature of this aspect is multidisciplinary, it would be interesting to propose the development of a ‘Good Practices Handbook’ for the elaboration of such medical social networks, which would comprise the insights of three different parties: academics and researchers, policy-makers, and the civil society, each with equal representation on the adoption of the measures. The discussion of the measures and problems should be two-folded: through online forum debates and physical gatherings with at least one element of each party.

FUTURE RESEARCH DIRECTIONS

The recent emergence of published research in the area of social networks and their application on Health has indicated both the failures of the software paths and goals for the prospective systems. In fact, it has been noted that software companies’ efforts over the last decade on the Health area have not eliminated medical errors as medical information is scattered instead of transversally integrated (Carroll, 2016). Indeed, as medicine is increasingly taking the path from reactive partner to health incidents, either individual or collective, to become a proactive agent, with a one-to-one preventive interaction between medical practitioners and citizens, the need to access integrated healthcare information is a cornerstone (Carroll, 2016). Further, the value of such synergy between the several parts in the health area, either as providers, such as hospitals, or recipients, such as payers, and even as both in different contexts, such as public health departments, has been positively assessed in the last two decades (Walker et al., 2005).

One can point out also that with the recent laws regarding privacy, such as European Union’s General Data Protection Regulation, and reinforced focus on encrypted data for security reasons of the rights of the common citizen, that the intersection of interests between medical social networks, medical information, public health policies and data security will become a field of research in the next two years, and its results taken into account in public health protocols.

Further, from a sociological perspective, social medical networks can simultaneously harvest from and deliver new seeds to the understanding of social capital and its applications, a field focusing on networks of people in a given society, as the concepts at its roots are akin to the social values and interrelationships between the individuals of a community. In fact, an indication that this emerging field could find an interesting spot in this research area is the number of studies carried out on health and social capital, which grew twenty times between 1995 and 2006 (Kawachi, Subramanian & Kim, 2008).

CONCLUSION

Medical social networks are simultaneously the frontier and avenue of effective health care systems. They allow a fast and feasible means to assess health care quality and monitor the three human components of the scenario: decision-makers, general population, and health professionals. However, and though a plethora of works presenting the advantages of cross-referencing social network data with online medical (and) social network data have been published in recent years, some questions still need to be addressed in order that the solution does not become a Kafkaesque nightmarish reality, namely the protection of the individual right to privacy. Within or outside the traditional frameworks of data protection, new proposals need to be made, while the system smoothly advances in scattered areas.

KEY TERMS AND DEFINITIONS

Data Protection: Process of protecting important information from corruption, compromise, or loss.

Information System: A software to collect, process, store, and disseminate information to support decision making, analysis, and visualization in an organization.

Medical Data: Health-related information that is associated with regular patient care.

Medical Network: A medical-based application of the principles of social networks.

Public Health: Health of the population as a whole.

Public Policy: Activities of governments acting directly or through delegation and influencing citizens' lives.

Social Network: A graph representing social interactions between individuals.

Ambiguities in the Privacy Policies of Common Health and Fitness Apps

15

Devjani Sen*Algonquin College, Canada***Rukhsana Ahmed** <https://orcid.org/0000-0003-0381-4491>*University at Albany, SUNY, USA*

INTRODUCTION

Mobile leisure, health, and wellness applications (apps) are ubiquitous. Research suggests that there are approximately 97,000 varieties of inexpensive and easy to use mobile health apps available in the market; at such a pace numbers are becoming outdated almost as soon as they are published (Privacy Clearinghouse, 2013). With approximately 320,000 of health and fitness apps in major app stores (Young, 2018), the question arises as to what happens to the sensitive data consumers enter into these apps, and what happens when these apps share data with advertisers and other third parties without the user's knowledge.

A growing topic of interest in both Canada and the U.S. concerns exactly what third parties can legally do with personal data. American law dictates that health insurance companies cannot discriminate based on a history of illness, specifically, severely restricting the dissemination and distribution of private health information without documented consent. However, while data held by a health plan, health care provider, or lab may be protected by the federal Health Insurance Portability and Accountability Act (HIPAA), legal scholars warn that if a patient is going to upload health or wellness data to a mobile application (app), it may not be covered by those laws (Rogers, 2014). Such legal ambiguities have implications for Canadian users of health and wellness apps, because many of these devices are based in the U.S., with the data being stored on U.S. servers and thus they may not conform to privacy requirements (Akkad, 2013). Clearly, such privacy concerns apply globally in any cases where personal data may be shared to third parties across two or more countries anywhere in the world.

There are some other important concerns with privacy and security issues related to mobile health and fitness applications (Huckvale et al. 2015; Rajindra et al. 2014). For example, personal apps collect all sorts of personal information like name, email address, age, height, weight, and in some cases detailed health information. When using such apps, many users may share a host of personal information and consequently make themselves targets to misuse of this information by unknown third parties. Moreover, according to Gralla et al. (2011), apps can gather the phone number and the unique ID number of each type of phone. In this way, personal information that apps gather about an end-user can be matched to these IDs, which means that ad networks can easily combine various pieces of information collected by multiple apps to build a sophisticated profile about a given end-user and thereby posing a major privacy risk to personal data. Therefore, un-informed decision by end-users raises important concerns regarding the ethics around sharing personal data gathered from health and fitness apps to third parties. To summarize, the issues raised above may be broken down to the following concerns:

DOI: 10.4018/978-1-7998-3479-3.ch127

- (1) ownership and veracity of sensitive data shared on personal apps
- (2) what end users really understand about the use of their data (what data are being collected and the specifics of how it may be used)
- (3) the ethics of sharing end-users' personal information and sharing it with third-parties

Despite the important role of informed consent in the creation of health and fitness mobile applications, the intersection of ethics and sharing of personal information is understudied and is an often-ignored topic during the creation of mobile apps. After reviewing the online privacy policies of a select set of mobile health and fitness apps, this chapter will conclude with a set of recommendations when designing privacy policies for the sharing of personal information collected from health and fitness apps.

BACKGROUND

Online privacy policies, which regulate the relationship between the user and the website with the purpose of limiting companies' legal liability during site use, are also employed by users to inform their understanding of the manners in which personal data are treated by companies. Despite their importance to users, however, studies suggest that these policies are often ignored (Angulo, Fischer-Hübner, Weastlund, & Pulls, 2012; Jensen & Potts, 2004; Kesan, Hayes, & Bashir, 2012; Tsai, Egelman, Cranor, & Acquisti, 2011). As pointed out by Steinfeld (2016), since agreeing to the terms of the policy is usually a prerequisite for subscribing to a website or a web service, users typically sign their consent almost automatically, so that these terms are rarely considered as reasons for joining or avoiding a given website.

Studies suggest that many apps do not have a privacy policy, or that apps do not grant users access to and control over personal information before users downloads and/or after using apps (Privacy Rights Clearinghouse, 2013). Nevertheless, having a privacy policy or providing a link to more information, is not enough to safeguard end-users' right to data privacy. Research suggests that innovative techniques must be developed to present information that was not possible with paper such that electronic formats do not simply mimic the metaphors of paper documents (Tansel, 2013). Research has shown that reading from electronic formats, such as the Web increases cognitive load and disorientation, and is consequently less efficient for learning (recognition as well as recall of information) than reading from paper documents (Eveland & Dunwoody, 2001). In their study of differences in cognitive processing when reading paper documents versus electronic documents, O'Hara and Sellen (1997) suggest a number of advantages to paper that need to be addressed in the design of digital systems. A chief advantage of paper, is the way it supports annotation while at the same time permitting quick and easy navigation, which in turn enables a reader to develop a sense of overall structure of the reading material. Furthermore, they learned that improvements in navigation and control of spatial layout of individual and multiple documents must also be supported in electronic documents. More specifically, studies have identified a number of cognitive factors which limit the comprehension of existing privacy policies, including complexity, legal language, and length (Angulo et al., 2012; Milne & Culnan, 2004; Nissenbaum, 2011; Tsai et al., 2011), use of vague terms and concepts (Anton et al., 2003), as well as design issues such as format and font size (Milne & Culnan, 2004).

IDENTIFYING PRIVACY RISKS IN HEALTH AND FITNESS APPLICATION PRIVACY POLICIES

15

Clearly, if privacy policies are not being read, there is a need for more readable policies that will be better understood and will more effectively inform users' decisions on whether it is prudent for them to join a given website service agreement. Indeed, given the varied educational levels and socio-economic backgrounds of online consumers that encompasses a wide range of the global population, it is critical that companies communicate effectively with customers through their online privacy policies (Wheatman & Ghiselli, 2014). With these considerations in mind, the purpose of the present chapter was to investigate the presence of important information and its presentation in plain language format in the privacy policies of health and fitness applications. Considering the limited scope of this chapter, the number of apps to examine was limited to four in order to properly execute a combined approach of using a checklist and discussing relevant excerpts from the selected privacy policies.

Health and fitness applications are software applications that offer health-related services on portable devices such as smartphones and tablet PCs. The apps examined in this chapter included: 1) Fitbit, which records data such as the number of steps walked, heart rate, quality of sleep, steps climbed, and other personal metrics; 2) JEFIT, a free app that records and logs fitness exercises, tracks workouts and progress, enables access to a large exercise database; 3) Nike Training Club, which gives the user a personal trainer, with more than 60 custom-built workouts from a Nike Professional Trainer as well as enables user to sync their results to social media sites such as Facebook to show friends how training is going; and 4) MyFitnessPal, a free calorie counter smartphone application and website, which helps to track calorie intake for exercise and diet and employs gamification elements to engage and motivate users to achieve their goals. In order to ensure that the health and fitness apps examined comprised popular apps with a wide user base, the selection criteria for each app was set at a minimum of one million downloads. Care was also taken to ensure that: a) each app had an androgynous user base, having an equal appeal for male and female users and b) two of the four apps in the sample included free apps considering such apps are expected to hold greater biases for selling material to third party sites. It is also important to note that the apps selected offer a diversity of core functions, including recording, logging and tracking personal metrics, diet, exercise and workout routines and progress, even working with certified personal trainers.

In order to assess the privacy policies of the selected four health and fitness apps, a checklist was used that comprised five privacy risk categories. These privacy risks were based on two questions: a) is important information missing to make informed decisions about the use of personal data? and b) is

Table 1. Checklist of Privacy Risks for Fitbit, JEFIT, Nike and MyFitnessPal Mobile Applications

Description of Privacy Risk	Fitbit	JEFIT	MyFitnessPal	Nike Training Club
Explicitly stated that under no circumstances will Personal Identifiers (PI) be shared	×	×	×	×
Use of cookies explicitly stated as well as what information is tracked and how it is used	✓	✓	✓	✓
Explicitly stated what sharing is done with third party sites and the security regarding links to other Sites	✓	✓	✓	✓
Location and use of personal data after account is deactivated	✓	×	×	×
Ownership of data is stated clearly when device is used by international users	✓	×	✓	✓

information being shared that might compromise the end-user's right to privacy of that information? The two authors of this chapter examined the online privacy policies of each selected app in search of important privacy risks. Based on their search, each author completed a separate checklist and compared their findings to reach an agreement of the presence or absence of each privacy risk category. Table 1 below outlines the results of the final checklist assessing the occurrence of each privacy risk examined.

The following section will discuss in further detail the subsections from the checklist from the assessment of the privacy policies of the four health and fitness applications.

Type of Data Collected Explicitly Explained and It Is Stated What Is Done with Personally Identified (PI) Data

Regarding personal identifiers, JEFIT states:

The information we collect in order to create your JEFIT.com account includes data such as your name and email address. The email address may be used to contact you with matters regarding JEFIT, such as a newsletter, notifications of new messages from other JEFIT members, or an announcement about a new product or service. We also collect some personal fitness information so that we can provide you with a personalized plan for successful weight loss. JEFIT also collects other profile data including but not limited to: personal interests, geographical location, gender, and age in order to assist our members find and communicate with each other. JEFIT collects personal information about you when you sign up for a JEFIT account. This information includes your age, metric preferences, and other personal fitness details. JEFIT also stores the data you enter about workouts, exercise, and anything you choose to track and keep records of.

When referring to non-personally-identifiable information, the policy states:

JEFIT also logs non-personally-identifiable information including IP address, profile information, aggregate user data, and browser type, from users and visitors to the site. This data is used to manage the website, track usage and improve the website services. This non-personally-identifiable information may be shared with third-parties to provide more relevant services and advertisements to members. User IP addresses are recorded for security and monitoring purposes.

From the above excerpts, it is not completely clear whether non-personally-identifiable information may be shared with third-parties. It is simply stated that personal information is stored and collected, without further explanation about the purpose of this storing and collecting. What does it really mean to use this data to provide the end-user with a personalized plan for successful weight loss? Does it mean sharing this information with third parties who can advise on how to best do this?

Further, in the section entitled Privacy Policy Change, JEFIT states:

When you use the JEFIT.com sites to provide personally identifiable information, you consent to the collection and use of that information in accordance with this privacy policy.

What does this statement convey? Again, the intended or planned use of the collected and stored personally identifiable information is not clearly communicated.

Finally, of the privacy policies of the four health and fitness applications explored, the most alarming ambiguity seems to be stated in the privacy policy of MyFitnessPal:

Except as otherwise provided in this Privacy Policy, and when You otherwise give permission or under the following circumstances, MyFitnessPal will not share Your Personal Information with third parties.

However, what is stated in subsection User Content, under Terms and Use, appears to conflict with (interestingly located in a poor visibility area of 19th bullet) MyFitnessPal's explicit statement regarding the PI data that the company can do whatever it chooses with the end-users personal data:

“User Content” is any content, materials or information (e.g., any text, information, photos, images, video, and other content and material, including nutritional information contributed to the Food Database) that You upload or post to, or transmit, display, perform or distribute by means of, the Services, whether in connection with Your use of Website, Application, or through the use of any Third Party Websites or Third Party Services or otherwise. You hereby grant MyFitnessPal and its officers, directors, employees, agents, affiliates, representatives, service providers, partners, sublicensees, successors, and assigns (collectively, the “MyFitnessPal Parties”) a perpetual, fully paid-up, worldwide, sublicensable, irrevocable, assignable license to copy, distribute, publish, transmit, publicly display or perform, edit, modify, translate, reformat and otherwise use User Content in connection with the operation of the Services or any other similar services or related business, in any medium now existing or later devised, including without limitation in advertising and publicity. You further agree that this license includes the right for the MyFitnessPal Parties to publish, display or otherwise use and make available your User Content and possibly your name and/or any user name of yours in connection with their exercise of the license granted under this section. You agree to waive, and hereby waive, any claims arising from or relating to the exercise by the MyFitnessPal Parties of the rights granted under this section, including without limitation any claims relating to your rights of personal privacy and publicity.

Regarding personal identifiers, Fitbit states the following:

We will never sell your data, and will only share personally identifiable data when you direct us to (or under the circumstances outlined in our Privacy Policy).

Although this information appears to be clear, it might not be understood the same way by different users. For example, many people might understand the above to mean that if they do not give explicit consent their data will not be shared. However, it could also be that directing data to be shared might occur in other more covert ways that most end-users are not aware of.

While NIKE does state in what ways PIs may be shared with other parties, they also explicitly state:

However, like other companies, NIKE cannot guarantee 100% the security or confidentiality of the information you provide to us.

Use of Cookies, What Information Is Tracked and How It Is Used

Most privacy policies of the health and fitness applications examined defined what is meant by cookies and what they do (how they track information) and give details about how to disable cookies. However,

many useful features of fitness apps warrant the use of entering in information that might be tracked by cookies. As Fitbit states:

When You Add Information to Your Account

You can customize your Fitbit experience by adding other types of information to your account, such as entering a food log or setting an alarm, personalizing your profile with photos, participating in discussion boards, or sending messages to your Fitbit friends. Whenever you add this type of data, we collect it and store it in your Fitbit account.

This statement raises the question of whether it is realistic for all cookies to be disabled. For example is it reasonable to expect a user to sign into a fitness app where they never enter information into food logs, set an alarm, participate in discussion boards, add photos to their profile, or interact with their friends who have this same app?

Sharing with Third Party Sites

On the whole, this section was well done by the four mobile application privacy policies examined. All apps stated that if end-users choose to share their information with Third Party Sites, they need to carefully read the privacy policies of these third party sites. This way, sharing of personal information with third party sites may likely happen with end-users' knowledge and based on their informed decision.

Location and Use of Personal Data After Account Is De-Activated

With the exception of Fitbit, it was not possible to clearly locate information on what happens to personal information once the user de-activates his or her account. Fitbit states:

You can deactivate your Fitbit account by contacting Customer Support. When you do, data that can identify you will be removed from the Fitbit Service, including but not limited to your email, name, photo(s), friends list and links to sites such as Facebook and Twitter. Backup copies of this data will be removed from our server based upon an automated schedule, which means it may persist in our archive for a short period. Fitbit may continue to use your de-identified data after you deactivate your account.

This statement raises two questions: 1) what happens to PIs during the short period of time referred to? and 2) what is the length of this period of time? Clearly more attention needs to be given to these important issues in terms of clarity and completeness of the information provided.

Ownership of Data Is Stated Clearly When Device Is Used by International Users

Only Fitbit clearly stated that the U.S. Privacy Policies do not apply to the sharing of personal data when using Fitbit devices outside the United States. Interestingly, although NIKE and MyFitnessPal also stated this information, it was missed entirely by one of the authors due to poor visibility. This may

be an important concern for international use of such devices by travelers from the U.S. in addition to end-users who reside in other countries.

RECOMMENDATIONS

Based on the review of the online privacy policies of four mobile health and fitness applications, and reflecting on the analysis of ambiguities and privacy risks in the privacy policies of those apps, the following recommendations are offered. Although these recommendations should be taken into consideration when designing privacy policies for the sharing of personal information collected from health and fitness apps, they can also be extended to the creation of privacy policies of mobile apps and web services in the areas of human resources, planning and project management, customer engagement, property management, education and training, among others.

1. It is suggested that personally identifiable information be stated clearly; PI and non-PI information should be clearly distinguished. It is also important to clearly state what will never be done with PI data. Moreover, this information should be made highly visible (within the first page) of any Privacy Policy/Terms and Conditions.
2. It was found that cookies were clearly defined in the privacy policies of the apps examined. However, given that information is tracked and used by cookies, the kinds of activities that enable activation of cookies might need to be stated more clearly.
3. Generally, when the end-user enters a Third Party Site, its privacy policies apply. While it is recommended that this guideline be stated clearly, the need to read and examine these third party site privacy policies should be highlighted as well. Furthermore, if Contests and Giveaways comprise Third Party sites, this information also needs to be highlighted; at some part of a Contest or Giveaway advertisement, it clearly needs to be stated that the privacy policy of this site is now in effect (vs. the privacy policy of the original site).
4. It is advised that information regarding the location and use of personal data after an account is disabled be stated clearly in the privacy policies. Not doing so may suggest that all data is automatically deleted upon deactivation of an account. Hence, it is recommended that this information be clearly presented under a subheading such as What Happens When Your Account is De-Activated or something similar to this.
5. It is proposed that the rightful owner of data be more clearly stated when devices are used by international users and this information be stated in a clearly visible manner.

FUTURE RESEARCH DIRECTIONS

This encyclopedia provides a comprehensive summary of research-based chapters on copious aspects confronting the field of information science and technology. Integrating ICTs into health care is complicated and it is a daunting process to create an ICT-driven health care system that is accessible, reliable, safe, and thus effective (Avtgis & Polack, 2013). Future research should proceed with caution when considering the design of health and fitness applications on mobile devices to help safeguard privacy when sharing personal information on health and fitness apps.

As explored in this chapter, mobile health and fitness applications raise many pertinent yet unanswered questions for health care ethics. Many end-users may automatically consider health and fitness apps to be beneficial; but, there are complications that may arise from neglecting privacy and security concerns when sharing personal information on these apps. Overall, ICTs help facilitate access to health information and thus can help to increase awareness which translates to patient participation in their own health care. There is an app for just about any health, fitness, and weight-loss resolution. Amidst this myriad health and fitness apps that are permeating lives all around the globe, an important question of data privacy looms large: what happens when advertisers and other third parties share this information without the user's knowledge? Questions like this and others that remain largely unexplored and that have only recently been asked by scholars should guide future investigations. Future studies should continue to investigate the complexities at the intersection of ethics and information sharing on health and fitness apps in order to tap into the potential of mobile apps to improve health behavior and health care delivery.

Health and fitness mobile application development should integrate the end-user experience perspective. Future research should privilege the end-user voice in determining ethics, privacy, and security of personal data shared on these apps, and in co-designing guidelines for data protection. Surveys, focus groups, and interviews can help gather important information regarding end-user awareness and comprehension of data privacy. Such data could yield valuable information to aid in designing simple and user-friendly privacy policies. Researchers across disciplines should continue to share good practices with regard to personal data use, sharing, and retention practices of health and fitness applications.

As the field of information science and technology continues to evolve, so do the available ICTs become integrated and may eventually be an integral part of the health care system. The end-users of mobile applications will have opportunities to influence developments in health information technologies that can lead to personalized tools to promote health and prevent disease. Yet, the intersections of ethics, privacy, security, and information sharing is understudied and is an often-ignored topic during the creation of mobile apps. In order to complement the research reported in this chapter, further exploration in the following areas is advocated for:

- A comprehensive review of privacy policies of the plethora of health and fitness applications that are available
- Full investigation, from the perspectives of both app developers and end-users, of ethical ambiguities in privacy policies across health and fitness applications
- An advancement of current understanding of how people with limited literacies – functional, health, digital, technology, and so on – use and apply health and fitness apps

CONCLUSION

Undoubtedly, the success of any emerging technology will depend to a large degree on the ability of people to use them effectively and efficiently. Today's health care system greatly depends on information and communication technologies. These advancements facilitate communication between patients, doctors, and other health care professionals. Through its review of topics such as the ethics of information sharing on apps and online privacy policies, this chapter helped to advance knowledge on the dangers of sharing personal information on mobile apps, which can jeopardize the rights to privacy of end-users of mobile apps. This chapter calls for multidisciplinary and multi-sectoral research partnerships to best meet the challenges of today's information technologies. Health and fitness mobile applications will not address

ethical and privacy concerns in and of itself. Researchers, practitioners, policy-makers, app developers, programmers, promoters, and users need to come together to debate and address these concerns.

KEY TERMS AND DEFINITIONS

Ethics: The critical examination of the advantages and disadvantages when deciding upon the correct conduct involving a moral issue.

Information Security: The process of protecting the availability, integrity and privacy of information.

Mobile Applications: A term used to describe Internet applications that run on portable devices such as smartphones and other mobile devices to make it easier for users to access the Internet.

Mobile Health and Fitness Applications: Application programs that offer health-related services on portable devices such as smartphones and tablet computers.

Online Privacy Policy: A document, typically required by law, which regulates the relationship between the user and the website with the purpose of limiting companies' legal liability during site use.

Personal Identifiers Information (PIIs): Comprises information, that when considered alone, or in combination with data from other sources, may contribute to distinguish (identify) an individual.

Privacy: An individual's right to control how and to what extent information about him or her may be shared and acted upon by others.

Generosity in Healthcare Policy Under the Obama Administration: Reflecting Various Dimensions Focused on the ACA

University of Victoria, Canada

INTRODUCTION

The goal of the Patient Protection and Affordable Care Act (ACA) was to achieve nearly universal health insurance coverage in the United States through a combination of policies largely implemented in 2014 (Obama, 2016). Several recent studies, including Frean, Gruber, and Sommers (2017) and Courtemanche et al. (2017), have shown that the ACA led to gains in insurance coverage. In fact, Patient Protection and Affordable Care Act (ACA) of March 2010 was to achieve nearly universal health insurance coverage in the United States through a combination of insurance market reforms, mandates, subsidies, health insurance exchanges, and Medicaid expansions (Gruber, 2011). These major components of the ACA all took effect in 2014, with the Medicaid expansion being optional for states after a Supreme Court decision. Nowadays, the Affordable Care Act (ACA) constitutes an effective public policy alternative that remedies some of the previous problems that existed in America's healthcare system (Gholipour and Rouzbehani, 2016; Rouzbehani, 2017). The ACA seeks to accomplish several fundamental objectives namely reforming the private insurance market, expanding Medicaid to the working poor, and changing the way medical decisions are made in end-of-life situations. All these objectives are rooted in private choices and expectations of rational decision making and incentives (Silvers, 2013). The objectives of the ACA, when examined from the perspective laid out above, in terms of the maximization of net value achievement, could be perceived in the context of the rational resource allocation policy model (Dye, 1981; Birkland, 2005).

BACKGROUND

The Affordable Care Act (ACA) expanded Medicaid eligibility to persons earning up to 138% of the federal poverty level, as part of the largest expansion of coverage to nonelderly adults since the 1960s. Although the expansion was originally intended to be enacted nationally, a 2012 U.S. Supreme Court decision made it optional for states. A total of 24 states decided not to expand in 2014, which affected 6.7 million uninsured low-income adults who otherwise would have gained eligibility. Since 2014, an additional 5 states have implemented expansions, although 19 states still have not adopted the expansion as of January 2017.

DOI: 10.4018/978-1-7998-3479-3.ch128

FOCUS OF THE ARTICLE

In this article, the author will discuss reports reflecting empirical studies of various dimensions focused on the ACA. As readers will note, these studies ranged from investigations of the apparent gender differences in support for the policy (Lizottle, 2015), the impact of the policy on dependent coverage mandate on insurance premiums (Depen and Bailey, 2015), and the implications of the ACA expansion to young adults in terms of inpatient hospitalizations (Antwi, Moriya and Simon, 2015).

Some of the findings presented in these empirical studies confirmed the proposition that the ACA has led to improvement and thus exercised a positive impact on the healthcare system in the United States. However, other findings (see for example, Garson, 2000) also point to the fact that there are still greater tasks ahead in producing a healthcare system that is both affordable and that ensures quality of care for all population groups in the United States.

Research Hypothesis

The central hypothesis of this research is that the ACA led to major improvements on the previous health-care policy of the United States. This hypothesis is predicated on the fact that the previous system was inadequate. Thus, in the previous system there were many problems with the private insurance market. There was also a need to expand Medicaid to the working poor and change medical decisions during end-of-life situations. Further, the need existed in the previous system to close the insurance gaps for young adults. This need arose out of the fact that in the United States the transition from adolescence to young adulthood was associated with the collapse of one's insurance coverage (Antwan, Moriya and Simon, 2014). Overall, the previous healthcare policy did not meet the affordability test and could not ensure quality of care for all segments of the population regardless of socio-economic status, gender, race, or creed. To buttress the hypothesis that the previous system did not meet the affordability test, Herzlinger (2010) noted that public healthcare spending in the United States threatened the economic welfare of the country because it was a poor value proposition in relation to its cost. Garson (2000) for his part, acknowledged the fact that to make the system more viable there was a need for more savings. The author proposed a variety of tools that would help accomplish this task (pp. 1048-52).

These are just a few of the many challenges that the previous healthcare policy could not meet. On the heels of these problems, hence, a new policy framework was set in motion with the passage of the ACA. In this paper, the efficacy of the ACA using the rational resource allocation model as a conceptual framework is assessed. Other theoretical approaches are also used to provide clarity on how political and institutional variables impinge upon policy development in the healthcare field (Gholipour and Rouzbehani, 2016).

Methodological Framework

Alternative approaches to policy formation are often governed by various policy models (Dye, 1981; Arnold, 1990; Mann, 1991; Birkland, 2005; Anderson, 2003; Kingdom, 2003). This researcher argues that sometimes even if government decides not to do anything in relation to a perceived policy problem, such decision may also be governed by a policy model (Birkland, 2005). Thus, policy models enable us to clarify our thinking about government, politics, and the policy process (Dye, 1981; Kingdom, 2003). They also allow us to make sense of the motivations of policy actors and consequences of policy alternatives (Dye, 1981, p. 17). For purposes of this discussion, I adopt the rational resource allocation policy

model. This model is being used as a theoretical and conceptual framework to justify the ACA. And by extension, to support the above stipulated hypothesis. Dye (1981) states that a rational policy approach is one that is designed to maximize what he refers to as “net value achievement.” Net value achievement is defined as a situation in which any sacrifice in one or more values required by a policy is “more than compensated for by the attainment of other values.” (p.27).

To arrive at this policy equation, the author also stipulates as a precondition that all relevant values to a society are known. As a matter of interpretation, I would argue that this definition of rationality is akin to efficiency—where efficiency is a ratio between valued inputs and valued outputs (Dye, 1981, p.27). The efficiency standard suggests that a policy is rational when it is most efficient meaning the ratio of the values it achieves and the values it sacrifices is positive and thus higher than any other positive alternatives (p.27). Dye’s (1981, p.27) idea of efficiency as he states involves “the calculation of all social, political, and economic values sacrificed or achieved by a public policy, not just those that can be measured by quantitative symbols.”

I also adopted a plethora of other policy models to complement the central conceptual and theoretical framework (Dye, 1981). These models include group theory, incrementalism and institutionalism. Group theory was used for example, to help account for the interaction and banding among groups of individuals with common interests. The model of incrementalism was also used to explain why the ACA was preferred over other radical alternatives. Here is how Kingdom (2003) described the model of incrementalism:

“Partly in response to writings which imply that a rational-comprehensive model either is or should be used in governmental policy making, Charles Lindblom and others developed their description and defense of an incremental approach. Instead of beginning consideration of each program or issue afresh, decision makers take what they are currently doing as given, and make small, incremental, marginal adjustments in that current behavior...The result is that policy changes very gradually, in small steps (p.79).”

The above definition aptly defines incrementalism as operationalized in this study. Similarly, the model of institutionalism was also used to shed light on the role played by governmental institutions in both promoting and resisting the ACA.

The Rationale of the Affordable Care Act

Series of empirical researches on the ACA have been conducted. What forms the core of this section are presentations of their findings on the ACA. The section also relies on findings found in reports and evaluative studies of the ACA. The analytical objective here is to show why the ACA became necessary to replace an existing policy alternative that was problematic in many ways. The findings presented here covered various grounds in terms of positing a rationale for the new policy—economic, political, efficiency, humanitarian and institutional.

Thus, Lizette (2015) in a study on the gender gap in healthcare policy preferences posits that there is a constant gender gap in healthcare policy preferences as such that women are more likely to support the Affordable Healthcare ACA than men. The study investigates two explanations for this outcome. The results show that the gap is connected to a larger debate in political behavior in terms of whether self-interest versus symbolic reasons drives public opinion. The author puts forward two central hypotheses: a) a humanitarian hypothesis and, b) an economic hypothesis. The study concludes that there is support for both hypotheses, and each partially mediates the gender gap in support for the ACA.

Another study conducted on the ACA found that the employers' mandate has led to a 2.5-2.8 percent increase in premiums for health insurance plans that cover children, relative to single-coverage plans. The study concludes that employers did not pass on the entire increase in premiums to employees through higher required contributions. This study is not unique as its findings are confirmed in other studies (see also Herman, 2015; Antwi, Moriya and Simon, 2015).

Moriya and Simon (2015) investigated the implications of the ACA expansion to young adults in terms of inpatient hospitalizations. The study focused on mental health related inpatient care and concluded that compared to those aged 27-29 years, treated young adults aged 19-25 years increased their inpatient visits by 3.5 percent, while mental illness visits increased by 9.0 percent. The study also found that the prevalence of insurance among hospitalized young adults decreased by 12.5 percent.

The broader implication of this study is that allowing young adults to remain on their parents' health insurance until they turned 26 years old was a rational approach in the context of the chosen conceptual framework. For example, the issue of mental health among young adults is a vexing one in an era of mass shootings, especially in the context of alternative approaches to controlling gun related mass shootings. Hence, any healthcare policy impact that increases early diagnoses and screening of mental health patients that may be prone to violence increases net value achievement from a societal and public health perspective.

The ACA was based on Massachusetts' healthcare reform, which preceded it. In effect, the Massachusetts' healthcare reform was a model for the ACA. One thing that the Massachusetts' healthcare reform shows is its ability to dissolve some of the ethnic and racial gaps that exist in access to healthcare. Maxwell et al (2011) conducted a mixed methods research to assess the extent to which it decreased disparities in insurance coverage and access to healthcare. The authors concluded that although disparities remain, there was an increase in insurance coverage among Hispanics. The research findings showed that increase in health insurance for Hispanics more than double that experienced by non-Hispanic whites (p. 1415). The paper also pointed out that language and other cultural factors were significant obstacles for Hispanics. It was recorded that only 66 percent of Hispanics with limited proficiency in English were insured (p.1415). The authors further reported that by 2009, one-third of Spanish-speaking Hispanics did not have a personal provider and 26 percent reported seeing a doctor because of cost. To sum up, these results were revealing as they confirmed a secondary goal of health care reform in Massachusetts, which was to reduce persisting ethnic and racial disparities in coverage (p.1415).

On the question of ending segregated behavioral healthcare, which was a feature of the previous system, McLellan and Woodworth (2014) argued that this practice was scheduled to change. Under the ACA, healthcare providers were mandated to provide prevention, screening, and interventions for the full spectrum of substance use disorders, not just addiction (p.542). Further, the ACA was also meant to make it possible for healthcare plans to carve in behavioral healthcare under their major medical benefit with the aim of improving total health outcomes (p.542).

In a study conducted by Huntoon, McClunney and Scannell (2011) it was found that 94.8 percent of medical students surveyed agreed that the pervious healthcare system needed to be changed. Also, 80 percent of those surveyed indicated that they supported the ACA and 78.3 percent indicated that they did not think that the reform efforts under the ACA had gone far enough. Meanwhile, a majority of those surveyed (58.8 percent) also said that they opposed repeal of the new healthcare law, while only 15.0 percent opposed repeal of the ACA. This finding was almost counterintuitive at the time given the fact that the ACA itself was very unpopular. The table below is just one among several pieces of empirical evidence that proves that Medicaid expansion under the rubric of the Affordable Care Act has yielded positive results.

Figure 1. Estimated reduction in uncompensated care costs in 2014 as a result of marketplace coverage and Medicaid expansion (in billions of dollars).

Source: *U.S. News and World Report*, 2015, p.1.

Source: *U.S. News and World Report*, 2015, p.1.

The figure(1) shows some differences in outcomes among states that accepted the implementation of Medicaid expansion (expansion states) and those who refused (non-expansion states) the implementation of this crucial aspect of the policy. Thus, while expansion states recorded reductions in uncompensated care cost amounting to 26 percent or \$5.0 billion dollars, those who refused to implement the provision recorded only 16 percent reduction in uncompensated care cost, which amounted to \$2.4 billion dollars. The next section examines the political and institutional forces that impinged upon the ACA's conceptualization, justification, and enactment into law and public policy.

Institutional, Ideological, and Political Forces

Like all policy alternatives, there were specific political and institutional imperatives that led to the enactment of the ACA (Hayes, 2007). Invariably, these processes have also influenced the pattern of implementation of the policy. Thus, to fully appreciate these variables in a nuanced fashion, and as mentioned earlier, this researcher adopted a plethora of other policy models to reinforce the central conceptual and theoretical framework (Dye, 1981). These models include group theory, incrementalism and institutionalism. Group theory is applied for example, to help account for the interaction and banding among groups of individuals with common interests (pp.21-4). This researcher also used incrementalism to explain why the ACA was preferred over other radical alternatives (pp.31-3). Similarly, the model of institutionalism was operationalized to shed light on the role played by governmental institutions and partisan interests in both promoting and resisting the ACA (pp.18-21). In applying the model of institutionalism, this researcher draws on the wisdom of Jacob Hacker and Paul Pierson's (cited in Riby, Clark and Pelika, 2014) when they intimated that:

“At the heart of politics is the exercise of authority. Winners of political contests are positioned to use the control of the coercive power of the state to impose their preferences on losers through public policies. The stakes are often vast, involving hundreds of billions of dollars and, literally, matters of life and death. Policies are not a side-show. For major political actors, especially the most well-resourced and enduring, they are the central object of contestation. Elections are just one means to the end of exercising authority through policy. Because policy is the central prize, it deserves a central position in the analysis of political systems—a position it has lost in modern political science, at a considerable cost to our understanding of politics (p.59).”

During President Barrack Obama's historic campaign to become president, he put forward a series of policy proposals to tackle most of the challenging issues that faced the nation. One of those proposals was his healthcare plan that he promised would revolutionize the public healthcare system in the United States. The President was committed to seeing through the implementation of his healthcare plan despite the exigencies of restoring the health of the United States economy. Before his ascension, the economy had experienced severe shocks due to the collapse of the housing market. In fact, one would argue that at this time the country was at a precipice---the verge of a second great depression.

Pressures also mounted from many immigration reform support groups that the president did something about reforming the immigration system. However, in the midst of all these pressures from many of his core groups of supporters, President Obama decided to fulfill his promise to reform a healthcare system that many regarded as underperforming, broken and costly. The main opposing party, the Republicans, was in combat mode, ready and prepared to resist changes to the existing healthcare system that did not confirm to their ideas and philosophies that they thought should govern healthcare reform.

The Republicans fiercely argued that implementing the ACA would lead to a federal government takeover of the healthcare system. The irony in the situation is the fact that the main provisions of the ACA were modeled after Republican initiatives that initially had broad bipartisan support (Lanford and Quandagno, 2015, p. 17). After President Obama signed the ACA into law, 26 states immediately challenged key provisions of the law by filing lawsuits (Lanford and Quandagno, 2015). In 2012, the Supreme Court ruled in support of most provisions. However, the Court also ruled that the mandatory Medicaid expansion was unconstitutional, thereby making the implementation of this provision optional for the states.

President Obama and the Democrats in Congress expanded great political capital to achieve what could only be described as a compromise. Indeed, the ACA was merely a compromise in the face of fierce opposition to address the failures of the healthcare system to provide affordable healthcare to millions of Americans. As a result the single payer-approach was taken off the table (The Nation, 2013). The fact that the much popular public option that would have established the foundation for a single-payer system was never proposed signaled an incrementalist turn in the market-based approach of President Obama and the Democrats (Dye, 1981; Anderson, 2003). In effect, the ACA would end up being just an attempt at incremental improvement to the existing healthcare system. But as mentioned above, the Republican Party remained hostile to the policy despite this compromised policy outcome (see Rigby, Clark & Pelika, 2014).

SOLUTIONS AND RECOMMENDATIONS

Lanford and Quandagno (2015) examined factors explaining Medicaid expansion and concluded that there were several predictors, including states' Medicaid policy legacy, providers' influence, racial resentment, and conservative ideology. Based on these findings, the authors concluded that enactment of legislation is only a part of the process of policy formation. The authors suggested that implementation and state dynamics are equally salient variables.

Lanford and Quandagno (2015, p. 8) also found that each of their measures of partisanship was highly positively correlated with movement toward Medicaid expansion statistically ($p < .001$). Thus, what the authors referred to as Democratic power was said to have a strong positive influence on movement toward Medicaid expansion, and Republican power had recorded a strong negative influence (p.8). The study also found that in states where people identified more as liberals, there was movement closer to

Medicaid expansion than states where people identified more as conservatives ($r = -.58$; $p < .001$) (p.12). Racial resentment in the study was found to also be more closely linked to Medicaid expansion decisions (p.12). Overall, the pattern of political behavior demonstrated by both parties with regards to Medicaid expansion and other provisions of the ACA is broadly consistent with David Truman's (see Dye, 1981, p. 21) conceptions of the group theoretic approach to public policy.

The issue of Medicaid expansion is at the core of the various factors that would make the ACA a viable policy alternative. Indeed, Medicaid expansion is as important as other provisions of the ACA, such as the abolition of preexisting conditions, the health insurance mandate, states' establishment of health insurance exchanges etc. Thus, contrary to initial expectations, over half of the states have refused to create their own health insurance exchanges (Hall, 2014).

More than half the states have refused to expand Medicaid, decisions that are usually based on party affiliation. Thus, all the states, as observed in studies mentioned above, that have refused to expand Medicaid are usually led by Republican governors or legislative majorities (p. 1459). The problem here is that states that run their own insurance exchanges have local control over the very kind of important policy and regulatory matters that conservatives complained the federal government usurps (p. 1459).

From a policy implementation standpoint, these are challenges that have confronted the full realization of the policy goals of the ACA. In addition, one would argue that the Supreme Court ruling in *National Federation of Independent Business v. Sibelius*, that held that states are allowed to opt out of Medicaid expansion, without sacrificing their current Medicaid funding, has undermined a major plank of the ACA. Critics on the left of the Democratic Party have also argued that the fact that the public option was not pursued means the ACA did not go far enough in instituting public health policy reform. These issues are currently playing in the Democratic Party with the rise of the Bennie Sanders' campaign for President of the United States.

Other critics have pointed at the absence of relevant provisions that would address the lack of price and quality transparency in the system (Herzlinger, 2010). Yet other politicians in the Democratic Party have called for the American healthcare system to assume features of the Canadian, British, and other healthcare systems in developed capitalist countries. In fact, it should be pointed out that the United States and Canada had similar healthcare systems in the early 1960s. It was not until in 1966, with the passage of the Medical Care Act (MCA) that Canada started on the path of what would become a truly universal system of healthcare (Roberts and Liu, 2014, p. 764).

FUTURE RESEARCH DIRECTIONS

A promising research can focus on a systematic effort to collect and "map" information on existing task-sharing approaches in rural and otherwise underserved settings in the United States and abroad using a mixed methods approach.

CONCLUSION

The ACA put in place profound changes in the way health insurance markets operate in the US and made coverage available for millions of uninsured or underinsured Americans. This paper posited that the Affordable Care Act (ACA) constitutes an effective public policy alternative that remedies some of the previous problems that existed in America's healthcare system. The central hypothesis put forward

in this paper is that the ACA is an improved alternative to the previous policy regime on healthcare. This hypothesis is supported by the rational resource allocation model. Empirical evidence reflected in prior studies was also adduced to support the hypothesis. The research concludes that further academic studies are required to go beyond current heuristic frameworks to deepen our understanding of how the ACA could be improved. It is suggested that understanding this unique challenge in the field of American public policy could only be achieved by effectively gauging some of the dilemmas and intricacies associated with evolving institutional and interest group politics.

KEY TERMS AND DEFINITIONS

ACA(Affordable Care Act): Contains comprehensive health insurance reforms and includes tax provisions that affect individuals, families, businesses, insurers, tax-exempt organizations and government entities.

Healthcare: The maintenance and improvement of physical and mental health, especially through the provision of medical services.

Insurance Market: The insurance market is simply the buying and selling of insurance.

MCA (Medical Care Act): The federal government passed the Medical Care Act in 1966, which offered to reimburse, or cost share, one-half of provincial and territorial costs for medical services provided by a doctor outside hospitals.

Medicaid: It is a health care program that assists low-income families or individuals in paying for doctor visits, hospital stays, long-term medical, custodial care costs and more. Medicaid is a joint program, funded primarily by the federal government and run at the state level, where coverage may vary.

Obamacare: An informal term for a federal law intended to improve access to health insurance for US citizens.

Policy Model: The rational model of decision-making is a process for making sound decisions in policy-making in the public sector.

Islamic Medical Ethics in Brunei Darussalam Hospitals

Syazana Fauzi

Universiti Brunei Darussalam, Brunei

INTRODUCTION

Today, one of the most pressing controversial debates pertains to the ethics surrounding the medical field. Due to the effervescent technological advancement, the lines between what is ethical and unethical are obscured. Thus, there is a necessity to draw a fine line between what is deemed ethical and unethical. In Muslim societies, any issues or concerns, including those relating to medical ethics, are addressed, and often resolved by issuing *fatāwā* (religious rulings), derived from the learned Muslim scholars' *ijtihad* (reasonings). These *ijtihad* stemmed from two principal knowledge sources, the Qur'ān and the Sunnah of Prophet Muhammad ﷺ. To clarify, medical ethical issues are essentially concerns faced in the medical field in general; however, they are discussed from an Islamic perspective in this chapter. The question that poses itself now is: what exactly is Islamic medical ethics? More specifically, how does it differ from the Western opinion of medical ethics? To grasp the difference between Western and Islamic ethics, particularly in a medical environment, it is important to understand that the connotation of ethics and law in the West is distinctive than that of ethics and law in Islam. What is generally meant by ethics here, according to the *Oxford English Dictionary*, is a set of rules that governs a person's behaviour, or conduct, activity, or action, based on his moral values. From a Western perspective, medical ethics are moral principles that apply values and judgements to the field of medicine, including clinical practice and scientific research (Beauchamp & James, 2013).

Medical ethics in the West functions as a guideline for medical professionals and scientists towards protecting and defending human dignity and rights of the patients (World Medical Association Declaration on the Right of the Patient, 1981), whereas for Muslims, both practitioners and patients are obligated to adhere to medical ethics as defined by Islam. Simply put, there are specific guidelines on how a Muslim should behave and what he should undertake for certain duties in a personal or medical situation. For example, it is imperative for a Muslim patient in a critical condition to practise patience, or *ṣabr*, and contentment, or *riḍā*, (two ethical manners encouraged by Islam), and to pronounce the *shahādah* prior to death. Thus, the moral principles of medical ethics in Islam are based on the *Sharī'ah*. Furthermore, what may seem like a moral issue in the West may actually be ethical and legal issues in Islam. For example, in cases of induced abortion. In some Western societies, a non-Muslim woman may have a right to abort her foetus without facing legal consequences. However, if a Muslim woman aborted her foetus, then such an act is illegal under the *Sharī'ah*, as agreed upon by the International Islamic *Fiqh* Academy. Therefore, the *Sharī'ah* sets ethical principles by which Muslim medical practitioners, researchers, as well as, patients, are guided by. In essence, what makes medical ethics "Islamic" is that these ethics are based on Islamic principles. These medical ethics and principles are extracted from the Qur'ān and the Sunnah, explained as well by the contemporary *fatāwā*, particularly for the purposes of this research, those issued by Brunei Darussalam's State Mufti.

DOI: 10.4018/978-1-7998-3479-3.ch129

The *fatāwā* of Brunei Darussalam's State Mufti are selected as this research exclusively looks at the context of Brunei Darussalam. Brunei Darussalam is a small Islamic monarchy, located on the north coast of the Borneo island in South-east Asia. On the first of January 1984, when Brunei Darussalam gained independence, Sultan Haji Hassanal Bolkiah officially proclaimed the concept of 'Melayu Islam Beraja' ('Malay Islamic Monarch' in English) as the country's national philosophy. Although Islam has been Brunei Darussalam's official religion since the declaration of the 1959 Constitution, and Islam has been long practised in the country since the first Sultan converted to Islam in the early 1360s (Elisseeff, 2000), most, if not all, of the medical practices and ethics implemented in Brunei Darussalam were not influenced by Islamic principles (*Brunei Annual Report 1983–1984*, p. 242). Even though Brunei Darussalam appoints an official State Mufti, who provides religious verdicts on various issues, including several ethical issues relating to healthcare, Brunei Darussalam's Ministry of Health implements the Good Medical and Dental Practice guideline, as part of their medical ethics. All practising doctors and dentists in Brunei Darussalam must adhere to this set of ethical guidelines, formulated by the Brunei Medical Board and adapted from the Good Medical Practice (2006), with the permission of the General Medical Council, United Kingdom. The guideline not only addresses doctors and dentists, but it also informs the public on what they can expect from the medical professionals.

Because of this separation of healthcare and religion, one may assume that the way medical practitioners handle medical cases might not coincide with the State Mufti's *fatāwā* regarding certain ethical issues. Thus, this research aims to analyse whether Brunei Darussalam's health professionals handle specific medical ethical cases in a manner that is congruent or incongruent to the State Mufti's *fatāwā*. In order to achieve this aim, this research conducts semi-structured e-mail interviews that were sent to a non-random sample of three hospital nurses working under relevant departments, such as the Operation Theatre Department, as well as, the Obstetrics and Gynaecology Department. All interviewees received the same set of questions, regarding how they typically handle cases of abortion, euthanasia, and organ transplantation (see Appendix 1). As some of the interviewees' responses overlap or are similar to each other, this research only presents their main ideas or arguments. As for Brunei Darussalam's State Mufti's religious opinions, relevant books discussing his *fatāwā* concerning certain medical ethical questions will also be utilised in this chapter. Analysing and comparing these qualitative data reveals the level of congruency between the State Mufti's *fatāwā* and the real-life medical practices in Brunei Darussalam hospitals. The findings for this research will contribute to filling some organisational knowledge gap, pertaining to how health institutions address some current controversial medical ethical issues from an Islamic perspective, particularly in Brunei Darussalam, a nation that is undeniably understudied as a case study, and one that claims to be an Islamic system of governance, as Islam is one of the principal components of its socio-political schema. Having considered the significance of this research, the next section reviews the various literatures on Islamic medical ethics.

BACKGROUND

Before delving into the literature review, the term Islamic medical ethics must be clearly defined first. For the purposes of this research, Islamic medical ethics refer to the application of Islamic principles to guide ethical or moral behaviour related to the medical and scientific fields, which specifically deal with human life (Shomali, 2008). There are many issues pertaining to ethics in medical healthcare. However, only three contentious ones will be discussed here: (a) abortion – on the right to abort a viable foetus, (b) euthanasia – on the right to live or die, and (c) organ transplantation – on the right to donate or ac-

cept an organ. Although medical ethics and principles in Islam are well-established as they are based on the Qur'ān and the Sunnah, research on their relevant application to the contemporary world has only emerged recently. For instance, Gatrad and Sheikh (2001) co-wrote a paper called 'Medical Ethics and Islam: Principles and Practice', in which they approached the subject matter by first defining medical ethics and providing a typology of medical ethics. Several ethical issues from an Islamic perspective are also covered in the paper. Examples of ethical issues include, but are not limited to, genetic manipulation, assisted conception, adoption, autonomy, organ transplantation, end of life, and brain death. The authors highlighted three sources of the *Sharī'ah*: the first two are the Qur'ān and the Sunnah, as the primary sources. And the third, but secondary, source is *ijtihād*, that is, the deductive reasoning, or interpretation, based on one's understanding of the *Sharī'ah*. Gatrad and Sheikh (2001) mentioned that these three sources contribute to the notion of Islamic medical ethics.

Significantly, they also included the *maqāṣid* as the guiding principles of Islamic Law. It is important to appreciate the *maqāṣid*, or objectives of the *Sharī'ah*, as they have helped resolve some of today's ethical and moral dilemmas by establishing the parameters of Islamic medical ethics. In other words, for a medical decision, or action, to be considered as ethical, such action must be considered in light of at least one *maqṣad*. For example, the procedure of in vitro fertilisation (IVF), for legally married couples recognised by the *Sharī'ah* who have difficulty in conceiving a child, would align with the fourth *maqṣad* on the preservation of progeny (Al-Bar & Chamsi-Pasha, 2015, pp. 173–186). Essentially, the three sources highlighted by Gatrad and Sheikh (2001), namely the Qur'ān, the Sunnah, and *ijtihād*, act as the guiding principles to formulate appropriate ethical rulings, according to time, place, and circumstances. Although their paper provides a good outline and serves as a theoretical framework for addressing contemporary ethical issues in scientific research, as well as, in the practice of clinical medicine, it did not discuss the practical application of Islamic medical ethics in the current healthcare field, especially in hospitals.

Another paper pertinent to this discussion is Padela (2007)'s 'Islamic Medical Ethics: A Primer', which deliberates upon the essence of ethics within the Islamic intellectual and juridical discourses. Within the Islamic intellectual dialogue, the relation between *adab* (appropriate manner or conduct) and *akhlaq* (character) is discussed, in which it is believed that *adab* literature intends to refine *akhlaq*. Alternatively, the paper explains that the ethical codes within the Islamic juridical discussion are often derived from the *Sharī'ah* and Islamic *fiqh* (jurisprudential understanding). Similar to Gatrad and Sheikh (2001)'s paper, Padela (2007) also explains the three different sources of the *Sharī'ah*, which are: the Qur'ān, the Sunnah, and, *ijtihād*. The Islamic codes on medical ethics are derived from these three sources. Padela (2007) also emphasises the concept of Islamic medical ethics in the context of *adab*, i.e., there are a set of proper conduct and professional, practical morals to be considered as a guideline of medical ethics in Islam. A comparison between the classical and modern of *adab* literature was also discussed in the paper. Although this paper clearly outlines the theory of Islamic medical ethics, there was neither an analysis nor a significant application on current real-life medical practices.

On the other hand, to provide a theoretical relevance relating to Islam under the Western concept of medical ethics, Mustafa (2014)'s paper, 'Islam and the Four Principles of Medical Ethics' investigates four key ethical principles pertinent to the Western medical field, as discussed by Beauchamp and Childress (1979), and the extent to which each principle is rooted in the Islamic literature. Thus, determining whether these principles, as a medical system or approach, are appropriate for Muslim doctors to utilise. The four principles of medical ethics are: beneficence, non-maleficence, justice, and autonomy. The author argues that "the concept of beneficence permeates through almost every layer of Islamic thought, from the material to the metaphysical" and mentions the significance of two of Allah's Names,

ar-Rahman (The Most Beneficent) and *ar-Rahīm* (The Most Merciful), several Qur'ānic verses, as well as, a *ḥadīth* (narration) to support his claim. The principle of maleficence is similar to the principle of *al ḍarar yuzāl*, that is, to remove harm, and the removal of harm takes precedence over an act with an equivalent benefit. Both Islamic and non-Islamic worlds view justice as a prerequisite when it comes to ethics, with no exception to medical ethics. As for the principle of autonomy and its relation to Islam, Islam also emphasises on an individual's responsibility and human rights' protection. However, in Islam, the Rights of Allah as the Creator are far superior to the individual rights of people, because all rights, including human rights, are determined by Allah.

Another paper that addresses medical ethics, specifically on abortion and euthanasia, from an Islamic point of view is Brockopp's (2008) 'Islam and Bioethics: Beyond Abortion and Euthanasia'. This paper discusses five articles, published in the *Journal of Religious Ethics*, relating to brain death, feeding tubes, gender selection, organ transplantation, and spiritual counselling. Brockopp (2008) also considers two broader implications, considering modern biotechnological advances: (a) the evolving definition of the human person, and (b) the ongoing importance of Islam in legitimising ethical responses to those advances. In light of the latter, there has been an attempt to establish a universal guideline on Islamic ethical principles in the medical field, thus justifying the ethical reasonings behind the general medical advances. The World Health Organisation (WHO) and the Islamic Medical Association of North America (IMANA) have each published their own guidelines on medical and health ethics from an Islamic perspective. Having discussed several available writings on Islamic medical ethics, the following sections will now discuss the three selected medical ethical issues: abortion, euthanasia, and organ transplantation. Brunei Darussalam's State Mufti's *fatāwā* pertaining to these issues will also be highlighted during this discourse.

CURRENT ETHICAL ISSUES

On Abortion

The first ethical issue relates to abortion. The burning question is: if a foetus achieves life-viability and its mother decides on abortion, then does discontinuing its life constitute murder? What about if the pregnancy is the consequence of a rape? In an Islamic juristic sense alone, abortion for any reason is considered illegal. However, as Islam emphasises on values such as compassion; it is important to reconsider the reasoning behind the abortion. Some '*ulamā*, or learned Muslim scholars, agree that in the case of abortion due to rape, abortion is only permissible before 120 days after gestation. From the Islamic perspective, the beginning of life – by Allah's *idhn*, or Permission, – usually occurs after this period. Therefore, it is forbidden to terminate a foetus after a spirit is breathed into the foetus by Allah's *idhn*. In the case of the *fatwā* issued by Brunei Darussalam's State Mufti, abortion in the case of rape is not sinful, as the action is done out of desperation (Abdul Aziz bin Juned, 2015, p. 3). Allah assures,

﴿فَمَنْ اضْطُرَّ غَيْرَ بَاغٍ وَلَا عَادٍ فَلَا إِثْمَ عَلَيْهِ إِنَّ اللَّهَ غَفُورٌ رَحِيمٌ﴾

...but if one is forced by necessity without wilful disobedience nor transgressing due limits, then there is no sin on him. Truly, Allah is Oft-Forgiving, Most Merciful. [Qur'ān, Sūrah al-Baqarah: 173]

The Prophet ﷺ also reassures that an unwilling sinful act done in a desperate situation can be forgiven by Allah. This reassurance is recorded in a *ḥadīth*, narrated by Ibn Mājah, on the authority of Ibn ‘Abbās, in which the Messenger of Allah ﷺ said, “Verily, Allah has pardoned (or been lenient with) for my *um-mah*: their mistakes, their forgetfulness, and that which they have been forced to do under duress.” (An-Nawawī). Thus, it is evident that if a rape victim aborts her baby, then she is allowed to do so, before the gestation period of 120 days, in an Islamic point of view. On the other hand, aborting an unwanted pregnancy due to voluntary adultery is forbidden at all cost, as Allah warns,

(وَلَا تَقْرُبُوا الزَّوَاجَ إِذَا كَانَ فَاحِشَةً وَسَاءَ سَبِيلًا)

And come not near to the unlawful sexual intercourse. Verily, it is a fāḥishah [(i.e., anything that transgresses its limits (a great sin)], and an evil way (that leads one to Hell unless Allah forgives him). [Qur’ān, Sūrah al-Isrā’: 32]

Unlike euthanasia and organ transplantation cases, where the Good Medical and Dental Practice guideline emphasises that doctors are to give rights to patients and families, in cases of abortion, the hospitals in Brunei Darussalam usually only deals with undeliberate abortions, as it is a crime to induce abortion, unless the doctors concluded that the mother’s health is in jeopardy (Syariah Penal Code Order 2013). In reality, there are no specific guidelines on how to handle these ethical issues, but there is a general guideline, which encourages doctors, patients and their families to make the final decisions or consent to the doctors’ suggestions. The following e-mail interviews with several hospital nurses will shed a light on how these ethical cases are actually handled in Brunei Darussalam hospitals. As for the first issue, a nursing officer, working in the Tutong Hospital, addressed the medical ethics in the cases of abortion:

In cases of abortion, patients will be admitted to the Obstetrics and Gynaecology ward through the Accident and Emergency Unit or through the Gynaecology Clinic. The patient will be monitored to determine whether it is necessary to perform the Evacuation of Retained Product of Conception (ERPC) procedure on the patient.

Another nurse, who is the Head of Obstetrics and Gynaecology Department in the Tutong Hospital, further elaborated:

[The way that the] doctor and nurses handle abortion cases depend on the case if the patient has complaints of bleeding or any complication, the doctor will do [an] ultrasound to find if any sac is still inside and to do blood test if any infection is noted. If a sac is found, [then] the doctor will admit the patient into the ward and give some antibiotic or blood transfusion if the patient’s blood Hb [level] is low. If the procedure fails, then the d&c [dilation and curettage] will [be] done in [the] operation theatre to remove the sac immediately, [supplied] continuously with antibiotic and iv [intravenous] drip. There is no such thing as complaining to upper authority. Just refer to medical social worker and ustazah [female religious teacher]. Nurses are only to follow what the doctor orders.

Having discussed Brunei Darussalam’s State Mufti’s religious opinion on abortion and two nurses’ answers on how they handle cases of abortion, the next section discusses the medical ethical issue of euthanasia.

On Euthanasia

15

At the moment, there is no exact definition of euthanasia that is agreed upon. *Stedman's Medical Dictionary* defines euthanasia as a quiet, painless death and the intentional putting to death of a person with an incurable or painful disease as an act of mercy through artificial means, whilst in the *Collins English Dictionary*, euthanasia is the deliberate act of killing someone painlessly, especially to relieve suffering from an incurable illness (Mason & McCall Smith, 1994, pp. 316). By comparing both definitions, there are common keywords consistent throughout, and they are: painless, intentional or deliberate, and incurable. Both definitions are similar in a way that to relieve suffering is deemed as an act of mercy. There are, therefore, two types of euthanasia: active and passive euthanasia.

Active euthanasia is an active intervention by a doctor to end life. In other words, an action with the intention to terminate a human life within a medical setting. Alternatively, when a doctor decides not to prolong life and withdraws treatments vital to maintaining a human life, it is passive euthanasia (*British Medical Association Report*, pp. 2–3), for example, switching off the oxygen support for patients who are unable to effectively breathe on their own. There are also other types of euthanasia, such as voluntary euthanasia, involuntary euthanasia, as well as, non-voluntary euthanasia. However, this chapter will only focus on passive euthanasia. The question now is: when an unconscious patient relies on a life support system to stay alive, who should have the final say, between the patient's family and the doctors, on switching off the life support system? For doctors, the legal indication of death is either the cessation of a heartbeat or brain death, in which a patient's heart only beats with the help of a machine (Atighetchi, 2008, p. 297). However, for Muslims, death is a Divine act when the soul separates from the body (Chishti, 1991, p. 123). If a patient relies on a life support system to stay alive, then doctors are usually certain of the patient's inexorable fate. The family of the patient may eventually learn to accept the patient's fate, or they may not.

The above issue then leads to the next question: would switching off the life support system be considered as a wise medical decision, a murder, or an act of mercy? If there is no hope in resurrecting a terminally ill patient who is in a vegetative state, then clearly, death is inevitable, and ultimately, Allah has the final decision on the patient's death. To tackle the ethical issue of euthanasia, Brunei Darussalam's State Mufti issued a *fatwā* regarding terminally ill patients who rely on life support machines. He affirmed that it is permissible to switch off the life support machine, if the patient is on the verge of death or the patient himself already gave his consent beforehand. The consideration of the patient's permission is regarded because the State Mufti judged the life support machine as a treatment, and the sick patient has the right to decide on the continuation of the treatment. However, the Islamic Fiqh Academy, an affiliate of the Muslim World League (MWL), issued a *fatwā* that prohibits euthanasia either at the request of the patient or a relative. Similarly, Omar Kasule, a prominent speaker in the field of Islamic Medical Ethics, asserts that "euthanasia violates the Purpose of the Law to preserve Life by taking life and it leads to cheapening human life making genocide more acceptable" (Omar Kasule, 2007). In the same paper, he continues to argue that euthanasia also violates the preservation of Faith as it is assumed that the cause of death is by Allah's Right, which is far from true, as there is a clear human involvement in both active and passive euthanasia.

As for cases of euthanasia, both nurses have similar answers respectively:

The doctor would meet with all of the patient's closest family members to discuss and explain the situation of the patient, and the nurse would only reinforce the information given by the doctor, and the nurse also acts an advocator for the patient himself and his family members.

The doctor will discuss with [the patient's] family members regarding terminating the use of life-supporting machine if [the] patient's prognosis is too poor, but the decision will be [made] by [the] family on whether they agreed or not.

The following section discusses the State Mufti's juristic opinion on the medical ethical issue of organ transplantation, followed by accounts of its real-life medical practice in hospitals.

On Organ Transplantation

The third and final ethical issue concerns organ transplantation, particularly on the rights of the living donor or the dead body, and the receiver. From an Islamic perspective, obtaining permission from the living donor is most important. Unless the living donor gave his permission before death, organ transplantation from the deceased to the living may not be allowed. However, the only exception for organ transplantation to be allowed in the case where the deceased did not grant his permission before death is by attaining the consent of the family of the deceased. According to Brunei Darussalam's State Mufti, if the deceased's family approves of the organ transplantation, then any organ is allowed to be transplanted to the receiver, except for organs that can be used for gender reassignment surgeries, such as ovaries. The State Mufti also emphasised several medical ethics to abide by on the process of removing organs from the deceased's body, including taking care of the corpse's *'aurah* and limiting the transplantation to only organs that are crucial for the receiver. Surgeons are also required to perform the surgery meticulously, only to the required extent, and the surgery should be performed in a quiet and peaceful environment to respect the deceased (Abdul Aziz bin Juned, 2015, pp. 114–115). On the other hand, in cases of organ transplantation, only some organ transplant procedures are performed in Brunei Darussalam hospitals. Most of the procedures are kidney transplantation, whilst other organ transplantation cases are usually sent to hospitals overseas. Both nurses agree to this fact:

[Most] cases [of organ transplantation are] done in Brunei. The transplants organ [are extracted] from [the patient's] relatives, siblings, wife or husband, with a variety of [compatibility] test done. Almost [all] kidney transplants [are] done in Brunei. [Both] patient and family will give consent for [the] organ transplantation.

For the time being, Government hospitals do not perform [some] organ transplant procedures. Patients will be sent to a hospital overseas to receive the surgical treatment or procedure of organ transplantation.

Having discussed all three medical ethical issues, the next section analyses the level of congruency between the real-life medical practices in Brunei Darussalam hospitals and the State Mufti's *fatāwā*.

SOLUTIONS AND RECOMMENDATIONS

The above interviews describe how nurses handle certain medical ethical cases, pertaining to abortion, euthanasia, and organ transplantation in Brunei Darussalam hospitals. One might ask, are these medical ethics congruent to the State Mufti's *fatāwā*? It is worth recalling that Brunei Darussalam's State Mufti declared that abortion, before the gestation period of 120 days, is not sinful, but only for rape cases. Passive euthanasia is deemed permissible, by the State Mufti, if the patient is on the verge of death, or

the patient himself already gave his consent beforehand. As for organ transplantation, the State Mufti also declared it permissible, as long as the patient granted his permission before death. Based on the nurses' answers, with the exception of organ transplantation, it is difficult to determine the circumstances of those cases, unless they are made clear. For example, in abortion cases, the patient may or may not confide to the *ustazah* (female religious teacher) the real reason behind her pregnancy, perhaps due to trauma or feelings of shame. Even for euthanasia, according to the State Mufti, the patient should be able to give his consent to switch off the life support machine. In reality, unfortunately, these cases are often decided by the patient's family instead.

Furthermore, there are no particular guidelines on certain ethical issues in the medical field, which in this case, relating to abortion, organ transplantation, as well as, euthanasia. Possibly in the future, Brunei Darussalam's Ministry of Health could consider the State Mufti's *fatāwā*, if they were to implement specific ethical guidelines for medical practitioners to apply in some complex medical cases. For the time being, clearly, there is still a level of secularisation between the medical field and religion. For example, although Brunei Darussalam's State Mufti issued a *fatwā* regarding abortion, the *fatwā* has not been included as part of the ethical guidelines in hospitals, yet. In Brunei Darussalam, medical ethics are clearly still separated from legal issues, even though in Islam, aborting a foetus is considered both an ethical, as well as, a legal issue. Perhaps, the biggest challenge that the Ministry of Health, or any other ministries, for that matter, faced is the lack of public articulation and socialisation before implementing a new strategy. The lack of socialisation and education of ideas to the public before the implementation of a new strategy may drive the public to be reluctant in accepting and welcoming the new change. If the Ministry of Health is successful in articulating new healthcare plans and guidelines that are in accordance to the *Shari'ah*, then the Bruneian society might just be more accepting of these strategies, as they understand that the implementation of these plans has not only social benefit, but also devotional significance, in terms of fulfilling the *fardhu kifāyah*.

FUTURE RESEARCH DIRECTIONS

The growing Islamic influence in Brunei Darussalam would probably lead to the implementation of more Islam-motivated health principles and medical ethics in Brunei Darussalam hospitals. But for the moment, further research is required, particularly on the functional relevance of Islam in the healthcare system. For example, when considering the existing cures recommended by Islam, mental institutions or psychiatric departments could start adopting an Islamic form of medicine, or spiritual healing, as an alternative for or in complementary with Western treatments (e.g., psychotic drugs and cognitive behavioural therapy). In this case, a different type of research is necessary to investigate whether such methods of alternative, or complementary, treatment are effective or ineffective on the mental state of psychologically ill patients. Further research could also specifically look at healthcare on the state level, on how much has the Ministry of Health incorporates Islamic principles and values into its healthcare system and organisation. This area of research would be a significant contribution to further understanding the health components of an Islamic system of governance, since people cannot function outside of a political and social organisation, i.e., no man can isolate himself from society. And creating a society conducive for the worship of Allah is the ultimate vision of an Islamic system of governance.

CONCLUSION

The findings demonstrate a certain degree of congruity, with the exception of abortion cases. Brunei Darussalam's State Mufti declared that abortion in cases of rape is not sinful, but legally, it would still be considered as a crime, as the current Brunei law (as of 2019) states that abortion is permissible only if the pregnancy is detrimental to the mother's health, as diagnosed by a medical practitioner in good faith. It is uncertain whether the Brunei Government will integrate the State Mufti's *fatāwā* into the Syariah Penal Code Order (SPCO) 2013, but on the healthcare side, absorbing the State Mufti's *fatāwā* into the medical ethical guidelines might just mitigate the disparity between healthcare and religion. If the Ministry of Health could articulate well the significance of Islamic principles and values in healthcare, then it would be another step forward for the Bruneian society to appreciate the functional relevance of Islam, perhaps not just in healthcare, but also in every socio-political aspect of daily life. If, and when, the society recognises Islam's functional relevance in its system of governance, Brunei Darussalam would then embody a society that is conducive for the worship of Allah, much like the Madīnian polity during the time of Prophet Muhammad^ﷺ. In achieving this vision, Brunei Darussalam could confidently assert to be a 'Negara Zikir', or 'Zikr Nation', as envisioned by the Sultan.

KEY TERMS AND DEFINITIONS

Abortion: An intentional act of eliminating an embryo or foetus, thus terminating the pregnancy.

‘Aurah: Parts of a body required to be covered by clothing in the presence of a non-*maḥram* (a person to whom marriage is permissible).

Euthanasia: An act of ending a patient’s life, either by injecting lethal solutions or depriving the patient of necessary treatments and/or nutrients.

Farḍhu kifāyah: Obligations to reach social sufficiency in an Islamic society. Failure to fulfil these social obligations would place the society under a huge sin.

Fatāwā (sing. Fatwā): Religious rulings that pertain to matters of the *Sharīʿah*.

Ijtihād: The reasonings, or opinions, or interpretations of a Muslim based on his or her understanding of the *Sharīʿah*.

Islamic Medical Ethics: When Islamic principles are applied as a guidance for ethical or moral behaviour in the medical and scientific fields that especially involve human life.

Organ Transplantation: A surgical procedure of removing a deceased patient’s organ and that organ is placed in the living beneficiary’s body as a replacement for the beneficiary’s damaged or missing organ.

Shahādah: Translates to “testimony” or “witness” in English. It is the first of the five pillars of Islam and is divided into two parts: *ashadu ‘alla ilāha illal’Lāh* (I testify that there is no god except Allah), and *wa ashadu ‘anna Muḥammadan rasūlul-Lāh* (and I testify that Muhammad^ﷺ is the Messenger of Allah).

Sharīʿah: Translates to “the way” in English. It is the Islamic Law that is derived from the Qur’ān and the Sunnah (Prophet Muhammad^ﷺ’s actions, sayings, and tacit approval).

APPENDIX**15**

The e-mail interview questions, pertaining to cases of abortion, euthanasia, and organ transplantation, are as follows:

- 1) How do doctors and nurses handle abortion cases in hospitals? Or are abortion cases being handled in private clinics instead?
- 2) How do doctors and nurses handle cases of euthanasia (a decision not to prolong life by terminating the use of life-supporting machines)? Who makes the decision to remove the life support? The medical team, the family or the patient?
- 3) How do doctors and nurses handle organ transplant cases? What kind of organ transplants are being performed in the hospital (e.g. heart, kidney, liver, etc)? Who gives consent for organ transplants, the patient or the family?

Distribution of Selected Health Technology in Regions of Slovakia

Beata Gavurova

Technical University of Košice, Slovakia

Matus Kubak

Technical University of Kosice, Slovakia

INTRODUCTION

Demographic aging processes in the countries have a major impact on the financial sustainability of healthcare systems. In Slovakia, as in many other countries, the proportion of the economically inactive population is increasing. The financial sustainability of the health system is very sensitive not only to aging society, but also to economic shocks. Demographic shift - increasing the share of the economically inactive population causes wage-dependent premiums to fall, while health spending may increase due to higher healthcare costs for older citizens. Therefore, the resilience and sustainability of the health system need to be ensured on an ongoing basis and prepared for changes in demographic structures in the countries. Attention is drawn to the role of ensuring more efficient use of available resources, and also maximizing health and well-being of the population (Dlouhý, 2009; Fragkiadakis et al., 2016). The health system's performance consists of three components: efficiency, availability and resilience. These three economic categories are also influenced by the distribution of medical devices and equipment, both by the quality of satisfaction of medical needs, by geographical availability and by the cost - the degree of financial burden on the health system. However, only few research studies deal with the issue of regional disparities in the use of selected medical technology. It is especially caused by problematic access to the data base, as well as insufficient attention to examining the impact of prevention programs on the effectiveness of the health system and their connectivity to early diagnosis and treatment. These facts present the main cause for executing this study. It aims in investigating regional disparities in the use of magnetic resonance imaging (MRI) in Slovakia during the years of 2008 – 2017, and their importance for assessing the availability and quality of healthcare in the Slovak health system.

BACKGROUND

Many foreign research studies examine the use and distribution of health technology in the regions of their country to explore different aspects of health care systems. Some research studies investigate health technology as a subject of a research, other than as a part of the methods in which they act as variables. As early as 1988, Stephan (1988) conducted a number of technology assessments in his study to help policy makers in decision making. The author states that despite the efforts, a certain degree of uncertainty in the assessment of health technology will always persist, so decision-makers must also accept the level of arbitrariness. Many authors have examined the distribution of health technology to ensure equal access to healthcare and eliminate regional disparities in their studies. Xing and Dyama (2016)

DOI: 10.4018/978-1-7998-3479-3.ch130

explored the burden of local public hospitals and their impact on the health care system. They identify a number of issues related to higher quality of healthcare and also the connection to technological innovation. Winchester and King (2018) analyse an uneven approach to healthcare in their study, declaring that decentralization cannot resolve this uneven approach in the country. Seymour et al. (2006) examined geographical aspects of imaging diagnostic equipment (IDE) for stroke suspected patients in Scotland. They used geographic information systems and analysed the availability of these health services. The authors point to the limited availability of stroke scanning services during weekends in the individual regions, and identify a number of recommendations for health policy makers. The macroeconomic view of this issue was the result of a study by Suzuki et al. (2018). Their study examined and analysed the relationship between the economic conditions of the OECD member countries and available resources in the health systems. The authors primarily focused on exploring the factors of implementation and use of the IDE. Altogether, 29 countries were classified into four groups according to medical environment and economic indicators. The number of hospital beds has been shown to have the greatest impact on CT and MRI numbers. The authors also plan to clarify other factors influencing the implementation and use of the IDEs by investigating high-growth medical equipment market. One of the causes of regional disparities in implementing of new IDEs may be an increasing complexity of health technologies. Also, it is proved by the results of Liljegren et al. (2006) study. The authors analyse the reasons of all the obstacles in implementing complex IDEs and look for appropriate methods to monitor these reasons. Marinic and Varga (2016) analysed diagnostic procedures and equipment for healthcare facilities in the context of the use of human resources in specialized fields: anesthesiology, gastroenterology, neurosurgery, pathology, microbiology, electrophysiology, neurology and cardiology. Data for analysis were obtained from all hospitals in Croatia in 2013 and the results were compared with available international recommendations. The results of the analyses pointed to significant differences between Croatian hospitals as well as international standards in Cost Utilization. The study has brought many implications to health policy. The research of organisational impact in the field of medical devices was researched by Roussel et al. (2016). Health Technology Assessment (HTA) is a rapidly developing area. Non-clinical areas have also been assessed in recent years. The authors emphasize the health-economic aspect, which has been the most prominent in the assessment of health technologies, while the organisational impact assessment has hardly been explored. Shah et al. (2015) investigated in their study an availability of health technology in particular types of healthcare - in injuries in Nepal. Their aim was to identify the factors causing regional disparities in the availability of health technology. The authors propose solutions to be cost effective and sustainable, linking them to an optimal planning process. The methodological aspect in relation to the use of health technology is examined in the study of, e.g. de Moraes et al. (2010). The authors investigated whether the Multicriteria Decision Aid methodology supports the creation of performance benchmarks within health technology processes. Also, the authors emphasize the need for multidisciplinary cooperation in the field of healthcare as well as cooperation between the different levels of management: operational and strategic. As authors state, the assessment of health technologies may only be successful with a multidisciplinary team approach. Similarly, the economic categories frequently appear in the studies as the target aspects of the IDE's research and use besides the technological processes. For instance, Wei et al. (2018) studied the relationship between hospital efficacy, and CT and Magnetic Resonance Imaging (MRI) in their study. They selected a random sample of 131 hospitals in China and conducted a questionnaire survey. Hospital efficiencies were measured by SFA, and subsequently planned to use DEA. A sample of hospitals was not chosen equally from a geographical perspective. The study also did not analyse inappropriate and appropriate use of CT and MRI, which the authors also report as a limitation of their study. Many authors used medical equipment

and devices as input variables within their analyses. Grosskopf and Valdmanis (1987), Zuckerman et al. (1994), Puig-Junoy (1998) and others used medical devices as a whole, as a variable. Bradford et al. (2001) used as a variable the usage of established and new technologies, Dey et al. (2006) used a capital equipment as a variable, which was defined as a current technology equipment to measure performance. Henry et al. (2013) investigated the impact of using new health technologies for early diagnosis and treatment, Tsekouras et al. (2010) monitored the impact of implementing new high-tech health technologies to increase production efficiency, Kounetas and Papathanassopoulos (2013) observed changes in the efficiency of Greek hospitals by introducing state-of-the-art medical devices. Many authors, such as Garmer et al. (2004), Hounbo et al. (2017), Postiche et al. (2018) had examined only selected types of medical devices, e.g. CT and MRI. Studies by Samut and Cafri (2015) belong to more recent studies and they are also interesting as they use as input variables number of MRI and CT devices calculated per 100.000 inhabitants, or Lee (2016) who used as one of the input variables the number of the MRI units, and others. The studies of Gavurova et al. (2017, 2018) were conducted in the Slovak environment and analysed the distribution of medical equipment and devices during 2008-2014. The presented study is linked to these results in order to investigate the regional disparities in MRI distribution in Slovakia, while using the correspondence analysis. The selection of this graphical method was determined by the objective of the study and the potential implications for health policy makers. The results of the analyses will be beneficial in the processes of creating national and regional strategic health plans, as well as in developing a strategic framework in the health system with an emphasis on assessing the availability of healthcare. This availability is linked not only to prevention programs as an input component of the health system efficiency, but also to the overall quality of health care as an output component, measured by the level of morbidity and mortality that is highly differentiated in individual regions of Slovakia.

DATA AND METHODOLOGY

In this study, we are focusing on the distribution of the magnetic resonance imaging scans within the timespan 2008-2017 in district town in Slovak republic. Dataset used in this analyse was provided by National Health Information Centre (NHIC), the state-funded organization founded by the Ministry of Health of the Slovak Republic. Slovak republic is divided on 79 districts (NUTS 4 level), among which 10 belongs to a two biggest cities Bratislava, and Kosice. And therefore, we distinguish 71 cities. Figure 1 depicts total magnetic resonance imaging scans in Slovak republic within time period 2008-2017. We can see on the figure that during period of 2008-2017, the total number of magnetic resonance imaging scans has increased from 33 magnetic resonance imaging scans in 2008 to 51 scans in 2017.

Figure 1. Total number of magnetic resonance imaging scans in Slovak republic within 2008-2017

Figure 2 describe the distribution of magnetic resonance imaging scans per 100 000 habitants during period of 2008-2017 (by the 31st of December 2018, Slovak republic had 5 450 421 of habitants). One can see, that magnetic resonance imaging scans has increased over time approximately 0.6 scans per 100 000 habitants in 2008 to approximately 0.94 scans per 100 000 habitants in 2017.

Figure 2. Number of magnetic resonance imaging scans per 100 000 habitants within 2008-2017

The distribution of magnetic resonance imaging scans over time among regions on NUTS 3 level in Slovak republic is shown on figure 3. Slovak republic is divided on the 8 regions on NUTS 3 level. In this study we distinguish 8 regions on NUTS 3 level, but we also isolated two biggest cities, Bratislava city and Kosice city, which have a large catchment area. Figure 3 indicates, that distribution of magnetic resonance imaging scans is profusely concentrated in favour of two big cities, Bratislava city and Kosice city. Bratislava city is strongly outlying even if compared to Kosice city. We see on figure 3, evident increase in number of magnetic resonance imaging scans per 100 000 habitants in Bratislava city. In Kosice city we document decrease in term of number of magnetic resonance imaging scans per 100 000 habitants over time. In other regions, where the number of magnetic resonance imaging scans per 100 000 habitants is close to 1 we document on average slight increase of number of scans over time.

Figures 4-11 describe magnetic resonance imaging scans equipment per 100 000 habitants in 8 regions in Slovak republic on NUTS 4 level during observed period. Figure 4 depicts situation in Bratislava region. We can see that best equipped is the Bratislava city within its city districts. All other cities have no MRI scans, except Malacky city from 2015.

On Figure 5, we can observe the number of MRI scans per 100 000 habitants in Trnava region during observed period. As in case of other region seat cities, we can observe the good equipment in Trnava city. From 2012, we observe very good facilities in Skalica city. By the end of the observed period we observe amelioration of situation in Dunajská Streda and Piestany.

Figure 3. Distribution of magnetic resonance imaging scans among regions in Slovak republic

Figure 4. Distribution of magnetic resonance imaging scans per 100 000 habitants among districts in Bratislava region

Figure 5. Distribution of magnetic resonance imaging scans per 100 000 habitants among districts in Trnava region

The situation in Trenčín region is on the Figure 6. We can conclude, that the region as a whole is underequipped by MRI scans and even the region seat city is well equipped only from 2014. Another middling equipped city in Trenčín region is Prievidza city.

Figure 6. Distribution of magnetic resonance imaging scans per 100 000 habitants among districts in Trenčín region

Figure 7 captures situation in Nitra region. Here we can note that by the beginning of observed period, the region was spatially well equipped by MRI scans. By the end of the observed period, three cities are well equipped by MRI scans. Nitra and Nove Zámky are well equipped in long run.

Distribution of Selected Health Technology in Regions of Slovakia

Figure 7. Distribution of magnetic resonance imaging scans per 100 000 habitants among districts in Nitra region

Situation in Zilina region is captured on Figure 8. In Zilina region we identify two cities which are well equipped by MRI scans from long run view, Zilina and Martin. Ruzomberok and Dolny Kubin are well equipped by MRI scans from short run view.

Figure 8. Distribution of magnetic resonance imaging scans per 100 000 habitants among districts in Zilina region

Figure 9 review the situation in Banská Bystrica region. Here we observe the amelioration of situation in Banská Bystrica region over time. From long run view, also Rimavská Sobota is well equipped city. From short run, Lucenec city is averagely equipped city.

Figure 9. Distribution of magnetic resonance imaging scans per 100 000 habitants among districts in Banská Bystrica region

Figure 10 captures situation in Presov region, which is the most populated region in Slovakia. Here we identify Poprad and Presov as well-equipped cities from long run view. On the other hand, we can see that Stara Lubovna and Humenne are well equipped cities in short time view. Levoca city starts to be very well equipped city in 2017.

Figure 10. Distribution of magnetic resonance imaging scans per 100 000 habitants among districts in Presov region

Situation in Kosice region, the second most populated region in Slovakia can be seen on figure 11. We can see, that in long run view, Kosice IV is the best equipped city district, but situation within this

area has degraded over time to standard observed in other cities in Slovakia. Otherwise, Kosice I and Kosice II are medium equipped areas. From short time view, Michalovce and Spisska Nova Ves start to be mediocre equipped cities.

Figure 11. Distribution of magnetic resonance imaging scans per 100 000 habitants among districts in Kosice region

Correspondence Analysis

Correspondence analysis is an exploratory quantitative technique intended for analysing data in pivot tables which aim is to reduce dimensionality. Correspondence analysis provides certain measures of correspondence between columns and rows of pivot table. Correspondence analysis is a popular technique especially when processing large pivot tables, where the graphical representation of the result is clearer than numeric outputs. This technique is descriptive and exploratory, which does not include testing of the statistical significance of the acquired results. Correspondence analysis is multidimensional visual technic that enable to graphically display columns and rows of the columns of the pivot table and specify the measure of correspondence between the columns and rows. The provided results are similar to results of factor analysis. Correspondence analysis deals with similar issues as the principal component analysis. In the correspondence analysis we study the relationships between the individual categories of two categorical variables. The output of correspondence analysis is two dimensional correspondence map. Coordinates in graph are analogous to factors in a principal component analysis. Correspondence analysis uses nominal variables as inputs and necessitate an existence of the dependence between the observed data.

In our study, we focus to determine similarities among district cities in Slovakia, according to average numbers of magnetic resonance imaging scans per 100 000 habitants during period of 2008-2017. To process data, we use a correspondence analysis. The quality of transformation of multidimensional points into the correspondence map is assessed by total inertia. The information about total inertia of our model is in Table 1. Our model captures by its two dimensions 83.1% of total inertia. First dimension contributes by 58.2% of inertia and second one contributes by 24.9% of inertia. It can be concluded, that our model captures 83.1% of reality, what is according to nature of processed data sufficient score.

Table 1. Proportion of inertia

Dimension	Singular Value	Inertia	Proportion of Inertia		Confidence Singular Value	
			Accounted for	Cumulative	Standard Deviation	Correlation
						2
1	.863	.745	.582	.582	.116	.006
2	.564	.319	.249	.831	.223	
3	.465	.216	.169	1.000		
Total		1.279	1.000	1.000		

Figure 12 is the correspondence map of analysis of number of magnetic resonance imaging scans in district cities in Slovak republic. Here we use the average number of magnetic resonance imaging scans per year during the observed period 2008-2017.

Figure 12. Correspondence analysis: Region/Number of magnetic resonance imaging scans per 100 000 habitants

The first finding is, that Kosice city and Bratislava city form outlying entities, where Kosice city corresponds to 10 magnetic resonance imaging scans per 100 000 habitants and Bratislava city to 3, 5 and 6 magnetic resonance imaging scans per 100 000 habitants. Cities in Presov region, Banska Bystrica region, Zilina region and Trnava region form second cluster that correspond to 2 magnetic resonance

imaging scans per 100 000 inhabitants. Finally, Kosice region, Nitra region, Trencin and Bratislava region forms third cluster that corresponds to 1 magnetic resonance imaging scan per 100 000 inhabitants.

FUTURE RESEARCH DIRECTIONS

In the Slovak health system, a process of hospitals' stratification is being prepared that should ensure its higher quality and efficiency. A major modernization of inpatient health care is planned as a part of the stratification of hospitals, while both, its efficiency and also improvement of the quality of health care are important. These parameters are linked to both, availability and health care security. All those parameters are influenced by structure and use of health technology in both, direct or indirect interactions.

Demographic development is also related to changes in health needs in Slovakia, which is also reflected in the number of hospitalizations. In 2017, there were registered 1.017 mil. of hospitalizations, while 72% of them were registered for acute inpatient health care. Consequently, up to 32 000 beds were used to treat them, while inpatient health care was provided by 139 general and specialized hospitals. There are also changes evident in the hospitalization time as the patient in Slovakia spends more time in the hospital than patients in the countries of the Western Europe with regard to the international comparison. Even if there is a higher rate of hospitalization in Slovakia, there is a lower rate of bedding.

Health policy experts are extensively addressing the sustainability of health and social systems based primarily on economic and demographic developments in Slovakia, as well as on changes in morbidity and health care demand, depending on the type of morbidity. Innovations and trends in healthcare are equally important as they affect the length and quality of treatment, as well as timely and quality diagnosis. By 2030, the hospitalization rate is expected to increase by up to 18%. These consequent facts encourage to perform a number of follow-up researches to investigate the impact of health care technology on morbidity and mortality, while taking into account the economic and geographical availability of healthcare in Slovakia. The projected increase in hospitalization rates is also associated with the planned change in morbidity patterns in the elderly as well as in prolongation of life expectancy. Early diagnosis of chronic diseases, which is reflected not only in economic aspects, but also in the quality of human life, is also drawn to attention. The subsequent research goal is to investigate the impact of availability of diagnostic and therapeutic medical equipment on the change in mortality and morbidity structure of the population. The extent to which the distribution of diagnostic and therapeutic medical equipment has an impact on the development of hospitalization as well as on changes in non-communicable diseases (NCD) is interesting. Similarly, those factors that determine the imbalance in the distribution of diagnostic and therapeutic techniques and reveal the barriers to their better use need to be examined in a cooperation with the health system institutions. This will serve as a motivation in creating optimal regulation mechanisms in order to balance healthcare availability and to eliminate regional disparities in a health. These research goals may also encompass the issue of prevention programs, especially in those areas that suffer from a negative development of some diseases for a longer period of time.

CONCLUSION

The growth of health care expenditures in Slovakia is considered the second highest of all the EU Member States, as confirmed by analytical outputs from the Ministry of Health of the Slovak Republic. Slovakia is one of the few countries that did not reduce the overall health care budget during the financial crisis.

In hospital and primary health care, there are persistent issues that need to be addressed in the context of demographic aging processes as well as the sustainability of the health system. The latest Strategic Framework on Health for 2014-2030 has made clear efforts to improve cost-effectiveness. The health of the population affects the country's economic growth and is influenced by many factors, and with increasing age, co-morbidities, complicating and increasing the cost of treatment, are also increasing. Strong technological advances bring many innovations in diagnosis and treatment, while new medical practices and the use of the latest technology place higher financial demands on the country's health system. Recently, the impact of medical technology on multiple aspects of the health system has been increasingly exploring and revealing ways to quantify and economize it. So far, such studies have been absent in Slovakia. The reason is a problematic data base as well as methodological difficulty. Therefore, the aim of this study was to investigate regional disparities in the use of MRI in Slovakia for the period of 2008 – 2017, and their importance in assessing the availability and quality of health care in the health system of Slovakia. As the analysis shows, the distribution of MRIs in Slovakia is intensively concentrated in large cities Bratislava and Kosice. The city of Bratislava has significantly more MRIs in comparison to the city of Kosice. In Kosice, there is evident decrease in the number of MRI per 100.000 inhabitants over the period under review. In other regions, the number of MRI per 100.000 inhabitants was close to 1, while on average, there is an increase in MRI per 100.000 inhabitants during 2008-2017. In Kosice, there are 10 MRIs per 100.000 inhabitants on average, and in Bratislava and its districts, there are 3, 5 and 6 MRIs per 100.000 inhabitants. The second cluster consists of the cities in Presov Region, Banska Bystrica Region, Zilina Region and Trnava Region, where there are 2 MRIs per 100.000 inhabitants. The third cluster with 1 MRI per 100.000 inhabitants consists of: Kosice Region, Nitra Region, Trencin Region and Bratislava Region. These results show considerable regional disparities in the availability of MRI in individual regions of Slovakia. These facts need to be studied in the context of the region's demographic structure, epidemiological analysis, as well as the number and types of healthcare facilities. The issue of optimum availability to specialized medical procedures requiring the use of MRI, resp. others is also raised. Insufficient availability may result in late diagnosis of very serious diseases that are highly costly to treat, accompanied by deteriorating quality of life. The research of MRI use in diagnostic and therapeutic processes for individual diagnoses and their linkage to the economic base remains research focus of this research team. Another important research area may be the investigation of the process and economic usability of MRI in the individual locations and a creation of potential regulatory mechanisms to eliminate regional differences. These may also affect the elimination of regional disparities in a health of the population, which is also declared in several international health programs. The results of these analyses will be beneficial for regional health plan makers as well as health policy professionals. The results of the study will support the implementation of comparative analyses and the development of national and international health benchmarks.

ACKNOWLEDGMENT

This research was funded by the Slovak Research and Development Agency under the contract No. APVV-17-0360: “Multidimensional analysis of significant determinants of public procurement efficiency with emphasis on the application of Health Technology Assessment in the procurement preparation phase”.

KEY TERMS AND DEFINITIONS

Access to Health Care: In general, it is the distance to a particular health care provider. It contains four basic dimensions: physical availability, economic (affordability from the patient's perspective), non-discrimination (including time availability) and information availability.

Correspondence Analysis: Correspondence analysis is a dimension reduction technique which results are displayed on the map so called correspondence map. Plotted points on the correspondence map represent the relative numbers of the pivot table. The points' position reveals similarities between the different row categories, between the column categories, as well as the relationship between them. Correspondence analysis show hidden relationships and the association between the analysed variables.

Health System: Includes all activities that support, renew and maintain health. It represents the social system of all institutions, organizations, and resources whose main objective is to improve population health through targeted prevention, restoration and maintenance of population health.

Health Technology: Is an intervention used to promote health, prevention, diagnosis and treatment of acute or chronic diseases, or in rehabilitation, etc.

Magnetic Resonance Imaging Scans (MRI): Represents the most accurate spatial imaging of soft tissues of the investigated site that is a direct insight into the interior without surgical intervention with maximum accuracy. It allows very detailed views of organs and tissues throughout the body without the need for X-rays or ionizing radiation. MRI employs strong static and low frequency time-variable magnetic fields along with radio waves that, in a connection with computer processing, produce images showing injury, disease process, or the presence of abnormal tissues.

Process of Demographic Aging: A process influenced by the prolongation of human life expectancy and the transfer of strong population years (1970s and 1980s) to higher ages. By 2030, there will be a significant increase in the population of people over the age of 75, which means expectation of increased consumption of health and welfare due to the declining rate of self-sufficiency of the age.

Regional Disparities in Health (Health Inequalities): Represent differences, disparities, and inequalities in health between individuals and groups. They are determined by the individual social position (income, education, employment, natural predispositions - genetics, innate immunity, etc.).

Sustainability of the Health System: It represents primarily fiscal sustainability in the health care sector. The Slovak health care system is largely funded by wage payments, funding depends directly on labour market participation and growing earnings. It is also affected by the growth of the economic burden index due to the higher age of the population.

Section 16

Medical Technologies

Expanding Scope of Information Technology in Clinical Care

Gumpeny R. Sridhar

Endocrine and Diabetes Centre, Visakhapatnam, India

INTRODUCTION

Clinical medicine deals with data in many forms. Conceptually it is suited to gain from information technology (IT) in terms of gathering, analyzing and putting data to practical use. However there has been a chasm, with experts from the two fields often unable to find common ground. The system developed at the Endocrine and Diabetes Centre (EDC) had its origin nearly 30 years ago; it was an end-user initiative followed by features addition by an IT expert. This is different from most earlier attempts where experts from the two fields tried to understand the needs and possibilities of each other with attendant bottlenecks in implementation.

When the EDC was set up 30 years ago, documentation was among the first priorities. Without losing focus of the primary aim, viz, patient care, the kind and quality of data was slotted to be developed into EMR format. Where the knowledge of the clinician was not sufficient to go ahead, collaboration with a software professional was sought; the latter could take over without glitches, because the product, developed until then, was geared in logic and technology to be taken over to the next stage. Importantly the evolution of the IT infrastructure was achieved without any interruption in patient care.

To our knowledge this is the first doctor-initiated EMR system, which was developed and evolved over nearly 30 years. The purpose of this chapter is to document its genesis and evolution and to point to future areas where it can be used. In its current iteration the project is being utilized at the point of care without disrupting the work flow, while retaining the advantages of data digitization and for allowing for addition of further features.

Clinical medicine aims to provide comprehensive care, which is personalized and predictive. As synergy between information technology and clinical encounters led to the electronic medical record (EMR) being the fulcrum of the health care system. What began as a 'electronic paper records' (Price M, Singer A & Kim J, 2013), has expanded to a much broader spectrum to be gathered, collated and utilized, adding digital images, sharing in real time, with the possibility in the near future to integrate other data including genomics and proteomics. In this chapter the evolution of EMR system at the Endocrine and Diabetes Centre is presented along with a blueprint of how it is planned to expand integrating future technologies and processes.

BACKGROUND

Conventionally, clinical medicine deals with data, obtained as non-linear, non-digital form. Paper medical records formed the bedrock for much of initial clinical research and progress. Despite their advantages re-use of data is not practical (Sridhar GR, Rao AA, 2009).

DOI: 10.4018/978-1-7998-3479-3.ch131

However in the management of non-communicable diseases such as diabetes mellitus, obesity, hypertension and coronary artery disease, a collaboration between the health care team and the patient is essential, with the patient sharing responsibility in self-care, outside of the physician's office. The rapid applicability of IT allows a practical means to do so. In addition newer digital technologies result in generation of large amount of data, which must be analyzed and used appropriately (Cahn A Akirov A& Raz I. 2017). EMR system has the many advantages of storing nearly unlimited data, with the ability to access, analyze and present it in a format that is easy to interpret, along with providing accurate and legible notes which can track the individual's lifetime of health status, medicine use, laboratory results, images from many sources, transferable across locations. They also provide clinical guidelines, flag abnormal results, remind tests to be done, and reduce medication errors (Sridhar GR, Rao AA et al 2009). In addition newer technologies allow remote consultation with physicians, electronic prescription and drug delivery along with feedback about medicine use (Poon EG et al 2006).

The initial hesitation of using EMR in the clinic, where, in the early stages, the physician seems to pay more attention to the computer or tablet screen than to the person sitting in front of her, is overcome with the many advantages of digital data (Doyle RJ, Wang N et al 2012). Integrating with older paper version of medical records is another major barrier for conversion into EMR, along with software issues in coding, customization, hardware maintenance, security and confidentiality (Pradeepa R, Prabu AV et al 2011). Newer skills are required to not lose emotional and eye contact with the patient. Essentially the EMR system must take into account the workflow so that it aids rather than hamper patient care. The bottom line is often the reluctance of physicians to use the newer systems. Despite all these, barriers not only from the end-users, but other stakeholders also, Serrano et al have concluded recently that health information systems could be beneficial in improving patients' quality of life and of care (Serrano A, Guzman JG et al 2018).

The EMR is ultimately integrated into a health information technology which includes decision-support systems which leads to cost saving at the system level (Ali MK, Shah S& Tandon N 2011).

The aim is to employ digital tools for individualized and upgraded delivery of medical care. Digital medicine has the potential to improve patient satisfaction, lower the cost of care, and enable clinical research not confined to merely academic centres (Stenholm SR & Topol EJ 2017). While information technology is ubiquitous, medical field has been untouched, except in isolated centres (Sridhar GR, Murali G 2011, Pradeepa R, Prabhu V et al 2011). Riddle et al (Riddle MC, Bakris G et al 2018) summarized the limitations of IT in the clinical practice: a general lack of harmony in the way data is collected and managed.

FOCUS OF THE ARTICLE

Evolution of the EMR system at Endocrine and Diabetes Centre (EDC)

When the EDC was established in 1988, patient records were maintained as text using paper files. With the aim of future digitized entry, the data was categorized into Identification (unique number for each new subject), Name, family name, gender, age, address, city and zip code. A second section related to the history of the patient, followed by the following sections on physical examination, investigations, treatment and follow up.

After two more years, the kind of (endocrine) diseases with which the patients presented was reviewed as well as the symptoms and signs for each. Data was separated into categories (eg in diabetes: duration

of diabetes, onset age, appetite, change in weight, weakness, shortness of birth etc); the main groups of diseases could be categorized into diabetes, thyroid, short stature, obesity, infertility and others (other disorders not fitting into the above categories).

Beginning of EMR

Next a basic EMR system was developed using database management system, having separate files for each condition (listed above). Each field in the feature-wise entry of the paper system was converted to a separate field in the database.

Down the line, Mr Venkat Yarabati who provided software support opined that although the next platform, Paradox was good, migration to a more recognized system was preferable, which is less likely to be taken off the market. Eventually his hunch proved correct.

The Next Step

To develop integrated software in MS Access, the disparate files (diabetes, thyroid etc) were all put together with three different files displayed together on the screen. Auto-generation of ID numbers as well as auto-save of data.

One file, common to all patients had the ID number, name, gender, age and address. A drop down menu provided a list of primary conditions, the second set of files, for which the patient presented (viz diabetes, thyroid, short stature, obesity, infertility and others). The third file at the bottom of the screen had fields for follow up data.

Calculated fields were added (viz, onset of diabetes by subtracting duration of diabetes from current age, body mass index from the height and weight fields etc). Besides, certain fields were blanked out depending on the gender or suspected condition (eg field on menstrual cycle was blanked for men; symptom and sign fields were appropriately presented or blanked for conditions of thyroid excess or deficiency).

In the follow up, only relevant portions of the first visit entries were displayed, along with data for a horizontal one-line entry at each visit. Feedback from the clinician is essential in arriving at these decisions. There was a periodical review and re-calibration of the system. To allow entry of other information, memo fields were included. Chronological display of important data provides a clearer picture of the course of disease and helps the clinician in taking corrective actions.

A printout of the generated form was given to the (new) patient at the end of the consultation. Depending on the data inputs, automatic advice was provided based on automated system generated print out, based on the rules incorporated appropriately (eg to stop smoking if the patient was a current smoker; to take care of the feet if there were symptoms or signs of peripheral neuropathy, or if the duration of diabetes was over 10 years, which is a risk factor, or if there were abnormal signs of the feet). Fields were also filled for the diagnosis (type 1 or type 2 diabetes, hypertension if the patient was on antihypertensive medicines, ischemic heart disease if the patient provided a history, different varieties of dyslipidemia depending on the values of the lipids in the fields for lab investigations. Similarly a numeric range was provided with a flag if the number exceeded it to avoid data entry mistakes.

An important first decision was taken to enter data in numeric fields even for qualitative data, because that would allow for analysis later on without transformation. Since only one person used the system initially, information was entered as categorical data: a number was assigned for differences in each symptom (eg '1' for normal appetite, '2' for increased appetite, '3' for decreased appetite etc for different variables).

The Next Step in the Evolution of the Database

Until this stage, all the data was entered by the clinician. In addition the prescriptions were hand-written. To improve the work-flow, a local area network was devised so that basic patient met the physician.

The Current Phase

The following software were used in the development of the current system: SQL Server 2012 as backend database, MS Access as front end, Access Reports for reporting and Microsoft Office Chart.

Password protected access to the EMR was devised. Those at the reception were provided access to adding a new patient along with her details, to enter the basic anthropometric and laboratory parameters, and the option to search whether the patient had registered earlier (based on the name and or family name) to avoid duplication. Mr Sairam worked on this aspect of the project.

This improved the efficiency of patient turn-around where routine tasks and entry of data are either automated or out-sourced at the reception so that the time of the patient and the physician are more efficiently utilized.

Practical Caveats

There were some practical lessons that were learned. Initially, the ID numbers were written manually and then entered into the EMR. This was error-prone and duplicate records were generated. From the outset an iron-clad procedure was followed for back up of data (every day initially, every week, later) on a hard-disk that is stored in a different physical location. It is very important to consider the possibility of hacking attacks or ransom-ware and therefore the system is best isolated from general internet.

Currently the data is stored in a separate server not connected to the internet, and all data being mirrored on a second hard disk in the server.

It is essential to bring across all users of the system together, and interact with the software developers. The difficult part is not for the software to be structured; difficulty arises in the health-care team providing the data that must be gathered and in which sequence. This needs effort, because traditional note taking entails non-structured free hand entry. Sufficient time must be provided for a balance to be struck between them. Without this, trying to put the system in place is likely to be fruitless.

On a literature search, the current system appears to be based on the database developed at the St Thomas Hospital, London (Carson ER, Carey S et al 1990). During the early 1970's when the London database was first begun, data was acquired by structured questions and later batch-entered into a main-frame computer. Twenty years later, the personal computer made it possible to both capture and record data simultaneously. Physical limitations of the hardware thirty years ago resulted in the presentations of data from 4,500 patients in comparison to the current system at EDC handling with data from more than 80,000 patients, and growing by the day.

Algorithms used for calculation of following items: body mass index, auto population of DX for Type 2 diabetes, categorization of diagnostic lipid disturbances diet prescription, calculation, patient search based on EDC Id, name, gender, city, mobile etc, patient appointment and fee calculator.

The workflow is provided in Figure 1

Figure 1. Workflow for the EMR at EDC.

SOLUTIONS AND RECOMMENDATIONS

With the system in its current iteration comprehensive and robust for clinical use, it stands ready to be interactive with and inclusive of data from other sources. An integration with the robotic biochemical analyzer allows for bar-coded samples to be analyzed and the results displayed on the physician's desk in real-time. With this and other devices for potential integration, collaboration between the instrument supplier and the software specialist is essential to allow transfer of data. Similarly an integration with the pharmacy the prescription can be sent ahead and the medicines delivered to the patient either by hand, or may be sent by post. A reconciliation software in the pharmacy will keep track of the stock available and send in automatic orders for medicines which are close to a pre-determined critical value.

Other digital data can be included in the patients EMR such as images of the eye fundus employing a digital fundus camera, thermal images of the feet, electrocardiographic tracings, ultrasound images, x-rays and clinical photographs. Images and recordings from all these sources can be captured, transmitted and stored in digital format.

Information from different sources can be integrated and retrieved in the patient's EMR . This saves time and effort of the physician while providing value for the cost of capturing data.

On follow up it will be possible to have a graphical representation of different parameters – individually or collectively.

Essentially, EMR allows for the capture and utilization of information and prevent medication errors to occur (Figure 2): patient identification errors, prescription error such as wrong drug, dosage and incorrect dose calculation, failure to adjust dosages in patients based on the patient allergies

Figure 2. Errors that can be prevented by EMR.

QUALITY OF CARE

The goal of these innovations is to improve patient care and outcomes. Quality can be measured on different domains such as clinical parameters, biochemical parameters along with economic and psychologic aspects (Kapur A 2001). It is important to differentiate between documentation and outcome, viz performing an action (biochemical test(s), clinical evaluation) versus improved outcome as a result of the action (Rao AA & Sridhar GR 2007. Iljaz R, Brondik A, Zrimec T & Cukjati I, 2017). A recent review suggested that decision-support tools having detailed features, interaction with patients accessible to them give better outcomes (Ali MK, Shah S& Tandon N 2011).

With the aim of improving coordination among health care team members by reducing missing clinical information, and providing support in clinical procedures, there is little real world evidence that EMRs truly improve outcomes in primary care settings. Crosson et al have shown that the mere employment of EMRs in primary care practices is not enough for improving quality of care (Crosson JC, Strickland PAO et al 2007). A synergy between EMR vendors and physicians using the EMR systems should be an ongoing process.

A literature review published in 2008 by Adaji et al, based on 24 articles that satisfied the pre-set criteria (out of a pool of 444 articles) showed that the use of information technology in diabetes care has the potential to improve diabetes care by improving interaction between the patient and the care

providers (Adaji A et al 2008). Even here, improvement in process measures was more than in outcome measures. Some of the impeding factors were, having to learn new skills, lack of adequate time, a fear of using computers and anxiety results from the need for change. These were overcome by training and by integrating the system into the usual process of care (Adaji A et al 2008).

On a more limited scale, healthcare information technology improved adherence to taking medicines from a review of 13 randomized clinical trials where electronic interventions were performed (Misono AS et al 2010). A critical aspect to success required a ‘substantial degree of patient motivation at the onset’ (Misono AS et al 2010). However the quality of studies were variable in rigour and duration.

Ciemins et al studied 495 adults with diabetes, initially provided with education to the primary care provider and. This was followed by EMR implementation (Ciemins et al 2009). Factors for success lay at the level of the system and at the provider. The intervention improved both processes and outcomes: at the end of the study, subjects were more likely to have received preventive screening, and to have better control of clinical risk factors. The system was developed and implemented ‘*to fit into tailored office workflow process*’ (Ciemins et al 2009).

A large quality related advantages of EHRs over traditional paper records was published from a large number of adults with diabetes (n:27,707) from 46 office practices (Cebul RD et al 2011). Following adjustment for covariates, there was substantially higher achievement of composite standards for care of diabetes among sites using EHR by 35.1 percentage points. Similarly, the composite standards achieved for outcomes was 15.2 percentage points higher in the EHR using sites. These were associated with improvement in care and outcomes as well (Cebul RD et al 2011). The authors concluded that appropriate use of EHRs may result in improvement in the quality of care in the population studied. Part of the reason for their better outcomes with EHR usage could be due to better quality of clinical decision support. The decision support system was not generic, but was targeted to improve standards of care.

A recent study from Slovenia added to the evidence that innovative approach using e-healthcare resulted in better self-management in subjects with diabetes who are not utilizing insulin for glycemic control (Iljaz R, Brodnik A, Zrimec T, Cukjati I 2017).

COST BENEFIT ANALYSIS

An AHRQ Publication on the costs and benefits of health information technology (HIT) prepared for the Agency for Healthcare Research and Quality (2006) analyzed 256 published studies on the benefits and costs of health information technologies. The cost-benefit analysis predicted that implementation of HIT could result in significant savings of cost. The benefits were projected to overweight the cost of investment.

Since implementing an electronic health record system has costs, not necessarily financial, the benefits could also relate to issues such as productivity, efficiency, decision-making and compliance to guidelines.

Barriers were related to situational, cognitive, physical, knowledge and attitudinal.

A more recent review on economic evaluation of health information systems was carried out based on publications between January 2000 and June 2012 (n:33). The authors concluded that concluded that economic evaluations were made with differences in methods, metrics and assumptions. However there was ‘some evidence of value for money in selected healthcare organizations and HIS types’ (Bassi J & Lau F. 2013). The caveat made by the authors that there was need for high quality studies of economic evaluation, with regard to six key components: ‘having a perspective, options for comparison, time frame, costs, outcomes, and comparison of costs and outcomes for each option’ (Bassi J & Lau F. 2013).

FUTURE RESEARCH DIRECTIONS

Merging and Integration of Data

While traditional data from clinical encounters and laboratory and financial is currently available, one must plan for the increasing availability of data from other sources such as genomics, proteomics and metabolomics. Improved technologies and plunging prices presage large amounts of data from newer technologies to be merged with clinical care. Issues of analysis, interpretation, usage and confidentiality are bound to arise.

Precision Medicine

Precision medicine refers to “..an approach for disease treatment and prevention that takes into account individual variability in genes, environment and lifestyle of each person” [<https://ghr.nlm.nih.gov/primer/precisionmedicine/definition>]. It requires integrating genomics and electronic medical records via research in basic sciences, clinical sciences and translational science (Ritchie MD et al 2015). Bertsimas et al reported that when personalised, diabetes management improved metabolic outcomes compared to the standard of care (Bertsimas D, Kallus N, Weinstein AM, Zhuo YD 2017). Thus the EMR will form the fulcrum where new data streams feed for a more comprehensive and individualized treatment. In the current phase, integration will be required across electronic record systems and genetic datasets, which differ in different medical centres. Reconciling these diversities will be a major problem awaiting solution.

Once the goal is met, physicians at their point of can access relevant genetic information in the EMR, which allows better diagnosis and resultant targeted care to patients (Ritchie MD et al 2015).

Issues of Consent and Privacy

Privacy and consent must be addressed in the march toward precision medicine (Sridhar GR, 2018). Often, consent is taken for a limited purpose in studies involving genomics; with further tests genomic data can be linked with EMR. The issue of consent if taken on paper becomes contentious. Therefore online consent obtaining procedures were suggested (Kogetsu A et al 2018).

Mutual trust between the investigator and the subject is essential. Considering the limitations of paper-based obtaining of consent, new methods were proposed where dynamic consent can be given online, ensuring interaction and continuity (Budin-Ljosne et al 2017). This allows subjects to either alter or remove their consent.

Issues of security in accessing data is a critical component in eHealth or the ‘use of information and communication technology for health’ (Budin-Ljosne et al 2017). Subject data can be encrypted, but authentication for retrieval needs equal attention. Currently, passwords are employed for authentication, which is prone to data leaks. Authentication of genuine user is required at the time of registration and at each log in.

For authentication, three broad methods may be used: ‘What one knows’, ‘What one has’ and ‘What one is’ ((Budin-Ljosne et al 2017). Authentication by what one knows may be a password or secret question, but the security is not sufficient. What one has may be a device or a token to generate a password, which is both inconvenient and prone to loss or theft. The third or what one is could be authentication, using biometry such as fingerprints or voice. It is not preferred as a single authentication method.

Currently, a two-step authentication method is preferable, consisting of a first-step password or equivalent, followed by the second step device or one time password (Budin-Ljosne et al 2017).

Defining Conditions and Diseases

Data is not often so clean and narrow in numeric form as in the EDC database; genomic data is linked to patient information stored in EMRs spread over institutions containing various types of data. To link genetic information with disease requires methods to define or at least describe the condition found in the EMR (Robinson JR et al 2018). Such efforts are worthwhile because longitudinal data of patients progress is available in EMRs, which can be linked to genomic and related data. Merging the two provides a fine tuned and nuanced picture of the phenotype-genotype correlation.

Before EMRs, phenotypes were curated from structured and unstructured data from a variety of sources including computerized billing codes, lab results, vital signs, use of drugs. Diagnostic coding of diagnosis provides a coarse-grained information, but suffers from changing coding criteria and errors in assigning codes.

The richest source of information is available in clinical documentation. Therefore, narrative text without uniformity must be processed using tools such as the natural language processing (NLP). General-purpose NLP systems are usable across a number of conditions, but they suffer from lower recall and precision compared to purpose-built approaches. For text-based annotation, NLP methods can identify sentence structure (Budin-Ljosne et al 2017).

Many methods were utilized in curating phenotypes: rule based, natural language processing, machine learning (including learning with noisy data, unsupervised phenotype discovery, hybrid approaches) and collaborative frameworks. A review of these methods was published recently (Banda JM et al 2018). *Rule-based* methods are appropriate where a clear diagnosis or procedure codes is available. *Phenomics* refers to the transdisciplinary field where genomic information is linked to phenotype data extracted from EMRs. It has a limited applicability when dealing with complex phenotypes or with datasets that are less standardized.

Where data are recorded in unstructured form as in discharge notes, radiology reports, pathology reports even in EMRs, information can be extracted by employing pattern-matching techniques against standard vocabularies (Hersch WR & Greenes RA 1990).

Currently, NLP is the common tool to extract electronic phenotyping; it is used along or along with rule-based techniques or statistical learning methods. *Symbolic techniques* depend on predefined semantic relationships, but with limited versatility. *Statistical model* is currently used more extensively in text processing. Both conceptual and contextual cues are utilized for phenotyping (Banda JM et al 2018). NLP is expected to play a prominent role in phenotyping efforts to both recognizing phenotypes as well as to process text and extract features needed for statistical learning.

Huang et al published a machine learning method to phenotype subjects with diabetes (Huang et al 2007). They employed feature selection via supervised model construction (FSSMC). The technique ranked 47 manually distilled features from an initial set of 410 structured variables. Using machine learning classifiers, naïve Bayes, C4.5 and IBI, those with highest performance were selected.

Support vector machines (SVMs) were employed for rheumatoid arthritis, an autoimmune disease. Associated rule mining method generated rules understandable by humans employing demographics, lab results and coded billing data (Banda JM et al 2018).

Other Sources of Data and Predictive Analysis

In addition to data from genomics, proteomics and metabolomics, data from other sources can also be integrated into the EHR: viz, vital signs (pulse rate, blood pressure, continuous glucose monitors, activity and sleep). A rich collection of phenotypic and genomic data would allow for machine learning techniques to predict the outcomes (Ritchie MD, 2018a). Practical demonstration of such use is available for predicting early eye changes in diabetes (Imani et al 2015). Proof of concept work was published in utilizing clinical variables to predict psychological outcomes (Narasinga Rao MR Sridhar GR ...et al 2010).

CONCLUSION

Clinical data lay scattered and often un-analyzable. Technology allowed the data to be organized in a manner that allowed it to be put to a lot more use than the original intention. With time the amount of information has burgeoned, requiring for a new eco-system to deal with it using information technology, workflow and methods to synthesize and utilize the data. Current improvements from clinical processes to outcomes must be addressed (Ali MK, Shah S& Tandon N 2011). Predictive modeling of diabetic complications and risk profiling is possible from analyzing data from electronic health systems (Liu B, LI Y et al, 2018; Marini S, Dagliati A et al 2016). Advances in combining clinical and genomic data (Kaiser J, 2018) helps in the transfer from the bench to the bedside (Sridhar GR & Murali G 2011). Integrating innovative advances in technologies into the health care system appears a key component in dealing with increasing health care costs and in an approach toward the goal of universal health care (Blood DE et al 2018).

KEY TERMS AND DEFINITIONS

Diabetes: A disease in which the body does not have enough of the hormone insulin.

Endocrine: Related to chemical secretions called hormones that serve as messengers to neighboring or far off cells.

Genomics: Relating to the study of genes, which essentially direct the function of cells in the body's cells.

Proteomics: Study of structure of proteins, which are produced as a result of the directions given by the genes.

Signs: The findings observed or elicited by the physician in a sick person.

Symptom: The complaints made by the patient as a result of her illness.

Artificial Neural Networks in Medicine: Recent Advances

16

INTRODUCTION

Medicine is a field closely coupled with and producing big data (Najafabadi et al., 2015), especially with the growing adoption of electronic health records (EHRs) in the United States (Bourgeois & Yaylaci, 2010; Mennemeyer et al., 2016) and the world (Wager et al., 2013, Appendix C). Medical big data serves as a critical resource for medical research and clinical decision making. Artificial neural networks (ANNs), along with other machine learning approaches, have been shown to be an effective method for analyzing medical big data to develop diagnostic and prognostic systems (Pastur-Romay et al., 2016).

Although ANNs have a short history of application in the field of medicine, with the first published research appearing in 1990 (Asada et al., 1990; Baxt, 1990; Dassen et al., 1990), there has been a continuing and growing trend of research investigating ANNs in medicine. Interestingly, two of the three articles published in 1990 were published in medical journals, while only Baxt's (1990) article on diagnosing heart attacks (myocardial infarctions) was published in an information technology journal, but he followed this work up with multiple publications in medical journals (Baxt, 1991, 1992). Searching the National Library of Medicine PubMed database for articles containing the term "artificial neural network" combined with any of the terms: medicine, medical, hospital, patient, diagnosis, prognosis, clinic, or pharma ([https://www.ncbi.nlm.nih.gov/pubmed/?term="artificial+neural+network"+AND+\(medicine+OR+medical+OR+hospital+OR+patient+OR+diagnosis+OR+prognosis+OR+clinic+OR+pharma\)](https://www.ncbi.nlm.nih.gov/pubmed/?term="artificial+neural+network"+AND+(medicine+OR+medical+OR+hospital+OR+patient+OR+diagnosis+OR+prognosis+OR+clinic+OR+pharma))) produces the results shown in Figure 1, which displays the annual increase in articles focusing on ANNs in medicine.

The amount of ANN in medicine research is even greater than depicted in Figure 1, since terms like "deep learning neural network" or "convolution network" or "evolutionary network," which are all types of ANN, are not included. Other researchers have also indicated a larger quantity of ANN research in medicine, with 473 articles in 1998 (Dybowski, 2000) as opposed to the 66 articles identified with the more specific search criteria. Other research claims an earlier start date, 1981, for the beginning of ANN usage in medical decision support (Miller, 1994), but here we report only those articles listed in the PubMed database.

ANN research in medicine is used to develop models and systems for a variety of applications including: decision support systems for both patients and surgeons, diagnosis, prognosis, resource planning and allocation, and variable significance and protocol heuristic evaluation. The goal of any research in the field of medicine should primarily be to improve the quality of life of the patient and secondarily to promote workflow efficiencies and cost reductions.

Next a brief definition of ANNs and a short historical perspective is presented. The purpose of this article is not to instruct researchers in how to develop an ANN, but rather to examine recent trends and

DOI: 10.4018/978-1-7998-3479-3.ch132

Figure 1. Medline/PubMed ANN articles in medicine as of July 15, 2020

advances in ANN research in medicine. Readers interested in a more general introduction to ANNs should examine the readings listed in the Additional Readings section. After the brief definition and historical background, recent research is described and trends in applying ANNs in medicine are discussed. Finally, future research directions are presented.

BACKGROUND

Artificial neural networks (ANNs) are a machine learning based classification and forecasting tool, based on modeling the neuronal activity of the human brain. ANNs come in a variety of architectures, which are represented by a large collection of interconnected processing elements called neurodes, and utilize a wide range of machine learning algorithms. These algorithms may be classified as either unsupervised learning or supervised learning or hybrid learning algorithms that utilize both unsupervised and supervised features.

Unsupervised ANNs learn classifications directly from the data they are analyzing and have long been used for image analysis in medicine, including mammography (Floyd Jr. et al., 1994; Leinsinger et al., 2006), MRI (Amatur et al., 1992; Wismüller et al., 2004), and other images (Jiang et al., 2010; Lin et al., 1996). Newer deep learning unsupervised ANNs are still being used for image classification and diagnosis based on images (Kallenberg et al., 2016).

Supervised ANNs require data with known outcomes to help guide the machine learning algorithms used in ANNs. Retrospective medical data is readily available from EHRs and other medical databases to serve as training data for supervised learning methods. Supervised learning ANNs have their neurodes arranged in layers, with increasing numbers of hidden layers enabling a higher degree of nonlinearity in the resultant model (Walczak & Cerpa, 1999).

ANNs have tremendous advantages for performing medical modeling (Tu, 1996; Walczak, 2008). These advantages include: ANN models are created using machine learning so arbitrarily complex non-linear relationships are identifiable; ANNs are nonparametric so prior knowledge of population and error distributions is unnecessary; once trained they are tolerant of noise in the data; and they are extremely fast even when working with very large data sets. Although research with ANNs in medical domains is growing rapidly, the main reason why ANNs have not been implemented and adopted further in clinical settings is their black box nature. The black box nature of ANNs does not enable causal analysis similar to logistic regression (Tu, 1996). Understanding causal relationships and identifying relevant variables is of significant importance in medical decision making (Hunink et al., 2014). However, this should not be seen as an impediment to implementing ANNs in medical decision support systems since various techniques exist to facilitate outcome explanations and assessment of the causal nature between the independent and dependent variables (Andrews et al., 1995; Guidotti et al., 2018; Olden & Jackson, 2002; Walczak, 2008). These techniques include rule extraction by examining the weighted connections (Augusta & Kathirvalavakumar, 2012; Zhou et al., 2003) and variable influence determination by leaving each variable and sets of variables out of the input set and evaluating their relative influence (Tu, 1996; Walczak, 2008).

CURRENT DIRECTIONS OF ANN RESEARCH IN MEDICINE

While research focused on ANNs in medicine is growing rapidly, adoption of ANNs in clinical practice is still lagging. Logistic regression is the principal modeling methodology employed in medical research (Dreiseitl & Ohno-Machado, 2002; Tu, 1996). Most ANN research presents a comparison of ANN prediction results evaluated against results from comparable regression models (e.g., Churpek et al. (2016), Fei et al. (2017), Futoma et al. (2015), Kim et al. (2018), Teo et al. (2018)), and this practice needs to continue for the time being, until most clinicians feel comfortable with ANNs. The ongoing need to compare ANN results against other more familiar statistical models, including regression, is not unique to medical domains. Comparisons of ANN results to other recognized techniques occurs across a wide variety of domains including: engineering (Kaytez et al., 2015; Khademi et al., 2017), geological and environmental sciences (Dou et al., 2018; Nourani et al., 2014), and physics (Kumar et al., 2015) among others. Until the research community accepts the general validity of ANNs, continued presentations of comparative models is beneficial to gaining acceptance of ANN medical models and systems.

In the last decade, the concept of deep learning and Deep ANNs has become a hot topic in machine learning research (Arel et al. 2010). Deep ANNs have proven to be beneficial, especially in sensory recognition and classification problems (Schmidhuber, 2015), such as detecting malignancies in medical images (Hinton, 2018). The definition of a “Deep ANN” is any ANN that has more than one hidden layer. The longer the path between the independent input variables and the dependent output variable, then the deeper the possible learning. One difference between Deep ANNs and more traditional supervised multilayer perceptrons and unsupervised Kohonen self-organizing map (SOM) ANNs is that the individual layers or collections thereof may alternately use different supervised learning or unsupervised learning training methods, thus combining both supervised and unsupervised learning into a single ANN network. It should be noted though that the idea of multiple hidden layer ANNs has been around since at least 1989 (Cybenko, 1989; Funahashi, 1989) or earlier and that the backpropagation learning algorithm created by Werbos (1974), which first enable multilayered ANNs (including the input layer, hidden layer(s), and output layer), does not pose any theoretical limit on the number of hidden layers

within an ANN. While no theoretical limit exists, the addition of each new hidden layer introduces another layer of complexity in the solution surface (e.g., introducing concavities to a convex solution surface) (Walczak & Cerpa, 1999) and in practice most medical research ANN models do not go past 3 hidden layers (Dahl et al., 2012).

From the PubMed data displayed in Figure 1, seven articles published in 2018 had deep learning or Deep ANN in their title (Cao et al., 2018; Gawehn et al., 2018; Grapov et al., 2018; Higaki et al., 2018; Pinaya et al., 2018; Prahs et al., 2018; Zanella-Calzada et al., 2018). A Google Scholar search for research published in 2018 containing the phrase “deep neural network” combined with some of the terms from the PubMed search, specifically: cancer, clinic, hospital, medicine, patient, or surgery; yielded over 17,000 results. From the Google Scholar search, some examples of items with the term deep learning or Deep ANN in their title include: scanning images for cancer markers (Ali et al., 2018; Bevilacqua et al., 2018; Salz et al., 2018), dentistry image scanning (Karimian et al., 2018), and retinal image analysis (Kermamy et al., 2018). These sample articles represent a very small portion of the research currently being conducted on the application of deep learning through Deep ANNs in the field of medicine.

Evolutionary learning is being applied to ANNs more frequently. The term evolutionary learning and also evolutionary ANN indicates that a biological model, which includes artificial life and genetic algorithms, is being applied to an ANN to determine the optimal network architecture or is being used in combination with ANNs to select input criteria or further improve the output classifications or predictions of the ANN. The idea of combining evolutionary learning, in particular genetic algorithms, to improve ANN performance started in the late 1980's (Miller et al., 1989; Montana & Davis, 1989), but has seen significant growth recently including the application of evolutionary learning to Deep ANNs (Arabasadi et al., 2017; Cui et al., 2018; Jiang et al., 2017; Li et al., 2018).

Besides Deep ANNs, a relatively new ANN methodology that is attracting attention for medical image and signal analysis is the convolutional ANN, abbreviated as either CNN or ConvNet. A CNN is composed of multiple layers and after the input layer, alternates between a convolution layer, which tries to match regions of an image or signal, and pooling layers, which condense the output from the convolutional layer into a smaller data set while maintaining all relevant information (Nebauer, 1998). Because of the multiple layers of CNNs, they should also be considered as Deep ANNs. Some CNN configurations specify an additional layer between the convolutional layer and the pooling layer which serves as an activation function to recognize relevant parts of the signal. These layers may be stacked to form multiple convolution to activation to pooling combinations until the signal classification achieves a desired accuracy. Examples of recent application of CNNs in medicine are: detecting myocardial infarction from electrocardiogram signals (Acharya et al., 2017), and detection of possible cancerous lesions for breast (Bejnordi et al., 2017), gastric (Hirasawa et al., 2018), lung (Yu et al., 2017), and pancreatic (Wang et al., 2018) cancers among others (Halicek et al., 2018).

ANNs provide the field of medicine with an efficient and reliable method for performing both non-parametric and nonlinear modeling using machine learning. While resulting classification and prediction models perform very well, a recent trend has emerged to try and further strengthen ANN results and possibly make their outcomes more understandable. This trend is the combination (or triangulation) of ANNs with other mathematical, statistical, and machine learning methods, including other ANNs, into single systems (Walczak, 2012). Smith (1993) indicates that all supervised learning ANN variables should first be evaluated using correlation analysis (e.g., Pearson's correlation matrix) to identify and remove highly correlated variables that can decrease ANN performance accuracy. CNNs, especially if convolution and pooling layers are iterated multiple times, may be considered as a form of triangulation that enables the output of earlier ANN to be used as input to a new ANN, which then improves upon

the prediction or classification of the image from the earlier ANNs. The term ANN ensemble signifies that a combination of ANNs are used with the output of one or more ANNs serving as the input to other ANNs. The idea of utilizing other machine learning methods in combination with ANNs was mentioned earlier in the form of utilizing evolutionary algorithms to improve ANN performance by determining optimal independent input variables or the form of ANN architectures. Traditional statistical methods may be used to help determine the optimal set of independent variables. An example of how to triangulate ANNs with other methods is the classification of genes related to cancers, which uses a statistical method, principal component analysis, to select genes to be considered in the input variable set and an ANN to classify the gene sets related to various cancers based on the variables determined by the principal component analysis statistical method (Chu & Wang, 2009).

ANN triangulation approaches to solving medical problems are varied and use a wide range of techniques in combination with ANNs. Table 1 displays a few recent examples of different techniques combined with ANNs in medical domains, demonstrating the growing trend of combining ANNs with other modeling strategies to gain the nonparametric and machine learning advantages of ANNs while diminishing any disadvantages associated with the black box nature of ANNs.

Table 1. Methods commonly combined (triangulated) with ANNs in medicine.

Triangulated Method	Medical Problem	Reference
Genetic algorithm (evolutionary)	multiple (diabetes, retinopathy) nasopharyngeal carcinoma	(Cortes et al., 2017) (Mohammed et al., 2018)
Mathematical/Statistical: k-means cluster correlation	Heart disease Pancreatic cancer survival	(Malav et al., 2017) (Walczak & Velanovich, 2018)
Other ANN (ensembles)	classifying white blood cells	(Rawat et al., 2018)
Combined: math/stat & ANN ensemble	blood pressure prediction	(Sadrawi et al., 2016)

ANN MEDICAL RESEARCH CONTINUING FORWARD

As stated above, the primary goal of research in medicine should always be to improve the quality of life of patients. This may be achieved through improved diagnostics to better understand and identify medical risks, improved treatment and outcomes assessment to improve recovery and understanding of outcomes, improved workflow and resource efficiencies to decrease the time required to obtain medical consultation or relief, and reduced costs to lessen the financial impact on patients.

Because ANNs utilize machine learning to model complex nonlinear problems, the results may be viewed as heuristic in nature and typically do not achieve 100% accuracy (both sensitivity and specificity). Research is ongoing to try and improve the performance of ANN models in the medical domain to better satisfy the goal of improved patient quality of life. As an example, some of the earliest ANN research was focused on predicting myocardial infarctions (Baxt 1990, 1991, 1992), a type of heart failure. ANN-based research on myocardial infarctions has continued (Baxt et al., 2002) and has sought to utilize new developments in ANN learning methods and architectures such as deep learning implemented in Deep ANNs (Acharya et al., 2017). A timeline of research examining the use of ANNs to detect or diagnose myocardial infarctions is shown in Table 2. We limit the results in Table 2 to 35 articles for readability, though many more exist for this specific medical diagnosis. As ANN researched progresses, in addi-

tion to utilizing newer techniques like convolutional and Deep ANNs, the research has shifted focus to not only diagnose myocardial infarctions, but also to diagnose other related coronary syndromes and to predict outcomes and survival related to myocardial infarctions, encompassing the full diagnostic and prognostic spectrum. As ANN research continues to try and improve on existing diagnostic, prognostic, cost savings, and resource allocation issues in medicine, the trend of expanding the focus of ANN solutions will continue and make ANN-based clinical decision support systems more encompassing.

FUTURE RESEARCH DIRECTIONS

Though ANN solutions in medicine have proven reliable and efficacious, many physicians and other clinical practitioners still remain hesitant to adopt this technology. The reason for this adoption reluctance as mentioned previously, ANNs are considered a black box and the consequent lack of information concerning causal relationships between the independent and dependent variables (Tu, 1996). ANN research should definitely continue and expand to be able to show applicability across all subfields of medicine and further continue research to provide mechanisms to automatically provide knowledge concerning the casual effects discovered by ANNs, since this knowledge is critical to medical research. Some ANN development tools, like JustNN (Neural Planner Software, 2015) imply variable causality by summing the absolute weights of connections.

Table 2. ANN research to diagnose acute myocardial infarction (AMI).

^{†††}also models infarct size

The expansion of ANN research to ultimately cover all fields of medicine is a desirable goal. One step in this direction that is needed is to make ANN solutions more generalizable. As an example, ANN research on predicting transfusion requirements has uniformly been targeted at predicting transfusion needs for patients of a single medical illness or procedure. Examples include ANN networks to predict transfusion requirements for coronary artery bypass (CABG) surgery (Covin et al., 2003), leukemia patients (Ho & Chang, 2011), and abdominal aortic aneurysm (AAA) surgery (Walczak & Scharf, 2000). Future research is needed to identify, using ANNs, those variables causally related to transfusion needs in humans and then develop ANN models that may be applied across a much wider range of surgery types and illnesses that may require transfusions. Ideally, new ANN research will produce a combined resource and prognostic model that is applicable to all classes of surgery. This approach of generalization should also be applied to other prognostic problems, including the anesthesia, physical and occupational therapy, and pharmacological needs of patients.

Electronic health records (EHRs) are widely used worldwide to improve patient care (Bourgeois & Yaylacicegi, 2010; Mennemeyer et al., 2016) and also serve as a data resource for ANN research (Bibault et al., 2016; Weng et al., 2017). As predicted by Kuperman et al. (2007) ANN diagnostic and prognostic tools need to become integrated into EHRs to provide decision support. ANNs are starting to be embedded into the clinical decision making process, especially in radiology (Pesapane et al., 2018). The integration of ANN diagnostic or prognostic models into EHRs, with a corresponding explanation facility, will provide another route for implementation of ANNs in practice. The need for moving ANN research into clinical practice is widely recognized (Khazaei et al., 2018).

The future of medicine is moving towards body area networks and implantable medical devices (IMD) to enable mobile data acquisition and treatment decision making. ANNs are already starting to be embedded within physical therapy wireless body area network devices (Lin et al., 2015), and this trend of utilizing ANNs in body area networks and IMDs will continue to grow. The integration of ANNs into an IMD requires the overall size of the implemented ANN to be small, but this is another future direction for ANN research.

CONCLUSION

ANNs are a machine learning method based on the neurology of the human brain and are useful for classification and prediction problems in medicine. Past research has demonstrated the efficacy of utilizing ANNs to perform diagnostics, prognostics, cost reduction, and resource allocation problem solving in medicine. The use of ANNs to model medical diagnostic, prognostic, resource allocation, and cost minimization problems is a growing trend for the foreseeable future.

KEY TERMS AND DEFINITIONS

Big Data: Is a term referring to an extremely large collection of data, typically in the petabyte range or larger. The data is only considered “big” if it taxes current state-of-the-art computing capabilities.

Diagnostic: Referring to the diagnosis or determination of a disease or diseases or trauma; defining the medical condition of a patient.

Kohonen/SOM: Is a type of ANN that uses unsupervised learning. Commonly used in audio and visual perception ANNs.

Perceptron/Multilayer Perceptron: Perceptron was an early name for a single processing element, now more commonly called a neuron or neurode. Multilayer perceptrons (MLP) are arrangements of perceptrons into layers, such as the input layer connected to a hidden layer which is then connected to an output layer. The abbreviation MLP is often used to refer to backpropagation trained supervised learning ANNs with at least one hidden layer.

Prognostic: Referring to the treatment and follow-up plan for a specific medical condition or type of trauma, for example, a course of chemo-therapy and radiation prior to surgery for the reduction and removal of a cancerous fibroid.

Sensitivity: The percentage of patients with a specific diagnosis or outcome that are correctly identified, which is the number of true positives divided by the sum of the true positives and false negatives.

Specificity: The percentage of patients who do not have a specific diagnosis or desired outcome that are correctly identified, which is the number of true negatives divided by the sum of the true negatives and false positives.

Internet of Things and Data Science in Healthcare

George Tzanis*Aristotle University of Thessaloniki, Greece***Ourania-Ioanna Fotopoulou***Aristotle University of Thessaloniki, Greece*

INTRODUCTION

Health care advances are taking place rapidly all over the world. The newest medical discoveries and the incorporation of best available evidence in medical practice have guided to serious improvements in human health and well-being. Life expectancy has been considerably increasing, leading to an aging population with different needs and desires. Moreover, world population has been rising exponentially, challenging the effectiveness of healthcare systems. New predictive tests, advanced procedures, and genomic therapy medicines have made medical care increasingly expensive, forcing cost containment even while overall effectiveness improves (Vasanth & Sbert, 2012). Nowadays, prevention and early detection of disease signs as well as quality of life are becoming the points of focus more than ever before. Furthermore, patient-centered medicine is deemed particularly important and promises better disease treatment for each individual. Patients are becoming better-informed, want to know more about their health and their treatment, and demand to be involved in decision-making regarding their health.

All the aforementioned trends and changes have revealed the necessity to adopt a different model of health care. The modern healthcare provision should be more patient-centric, rather than career-centric, in order to deal effectively with the new challenges. Such a healthcare system should be organized in a layered structure (Pang, 2013) as shown in Figure 1. For example, the lower layer should comprise the single person and the higher one the hospital. Between these two terminal layers one can find the home and community layers. The lowest layer (person) is characterized by the lowest labor intensity and operational cost, as well as the highest frequency of usage for chronic disease and lowest frequency of usage for acute disease. In contrast, the highest layer (hospital) has the highest labor intensity and operational cost, as well as the highest frequency of usage for acute disease and lowest for chronic disease.

The delivery model of health care is now standing at the starting point of its way to transform from the traditional hospital-centric to the modern home-centric/person-centric approach. The Internet of Things with its pervasive, personalized, and ubiquitous character can guide health care through this way. Many relevant concepts have been introduced to describe the future healthcare model powered by emerging information and communication technologies. Various terms, such as connected health, health Internet of Things (Health-IoT), pervasive healthcare (pHealth), ubiquitous healthcare (uHealth), mobile healthcare (mHealth), electrical healthcare (eHealth), telehealth, telemedicine, etc., have been utilized in order to express the plethora of these new concepts (Pang, 2013; Pawar et al., 2012; Rose et al., 2015). All these new concepts include, more or less, the fundamental aspects of the home-centric/person-centric healthcare model.

DOI: 10.4018/978-1-7998-3479-3.ch133

This article presents the concept of the Internet of Things as applied in health care discussing the benefits and opportunities as well as the posed obstacles and challenges. The article focuses on the basic strategies for analyzing healthcare data generated by the Internet of Things enabled devices and describes the current status, the major challenges, and the future trends of this revolutionary field.

Figure 1. The layered structure of a modern healthcare system

BACKGROUND

According to the definition provided by the telecommunication standardization sector of the International Telecommunication Union (ITU-T Recommendations, 2012), the Internet of Things (IoT) is “a global infrastructure for the information society, enabling advanced services by interconnecting (physical and virtual) things based on existing and evolving interoperable information and communication technologies”. With regard to the IoT, the term “thing” is defined as “an object of the physical world (physical thing) or the information world (virtual thing), which is capable of being identified and integrated into communication networks”. Exploiting various capabilities, concerning identification, data capture, processing, communication, etc., the IoT uses any “thing” to offer any service to any application domain. At the same time IoT has to abide by the requirements for security and privacy (ITU-T Recommendations, 2012).

The term “Internet of Things” was first used by Ashton in 1999 to refer to the linking of internet and the interconnected objects via radio frequency identification (RFID) technology. (Ashton, 2009). Undoubtedly the IoT is the future of technology, with societal implications as well, that can make everyday life more efficient. The IoT can be recognized as the second digital revolution (The Government Office for Science, 2014), given that the first one was the World Wide Web, which connected people around the world establishing a global community. The IoT is built on the basis of the World Wide Web extending its benefits and opportunities, but poses new big challenges. It is expected to greatly integrate leading technologies, such as technologies related to advanced machine-to-machine communication, autonomic networking, data mining and decision-making, security and privacy protection, as well as cloud computing, with technologies for advanced sensing and actuation. As shown in Figure 2, the IoT

Figure 2. The new dimension (any thing communication) introduced with the Internet of Things (ITU-T Recommendations, 2012)

adds the dimension “any thing communication” to information and communication technologies (ICTs), which already provide “any time” and “any place” communication.

In general, IoT architecture can be described as a four-tiered multilayered structure (Da Xu et al., 2014). From the bottom-up, the first layer is the sensing level, which integrates with all the different types of hardware (RFID, sensors, actuators, etc.) that are connected to the physical world and collect data. The second layer is the networking layer, which provides networking support and data transfer over wired and wireless networks. Next is the service layer which creates and manages all types of services to meet user needs. Finally, the interface layer, which is on top, provides interaction with users and other applications.

Among the plethora of application domains that can benefit by the utilization of the IoT, health care is one of the most important. IoT Analytics, a leading provider of market insights for the Internet of Things (IoT), Machine to Machine (M2M), and Industry 4.0, has identified the top 10 IoT segments in 2018 (IoT Analytics, 2019) and Connected Health is one of them. The other segments include in the list are Smart City, Connected Industry, Connected Building, Connected Car, Smart Energy, Smart Supply Chain, Smart Agriculture, and Smart Retail. Their study utilized data from a structured repository of 1,600 real-world projects that were either ongoing or had been successfully completed. All these projects

were classified as non-consumer IoT implementations. According to IoT Analytics, the most popular IoT segment for 2018 was Smart City, including 367 projects out of 1,600, followed by Connected Industry (265 projects) and Connected Building (193 projects). The geographical distribution of these projects is the following: Americas (45%), Europe (35%), and Asia (16%). Europe includes the majority of Smart City projects (45%), whereas the Americas embrace most Connected Health (55%) and Connected Car projects (54%). Smart Agriculture projects (31%) are most popular in the Asia/Pacific region.

Vilamovska et al. (2009) have classified IoT applications, in particular RFID applications, in healthcare across two axes:

- **IoT enabling functions:** These are four key and mutually exclusive functions concerning assets, staff and patients.
 - Tracking.
 - Identification and authentication.
 - Automatic data collection and transfer.
 - Sensing.
- **Healthcare applications:** These are the four most promising areas of applications in healthcare as identified by Vilamovska et al. (2009).
 - Patient safety and quality of care.
 - Pharmaceutical application (not including supply chain and counterfeit drug issues).
 - Management of devices, supplies and biological material.
 - Patient and healthcare provider support and management.

Examples of healthcare applications for each enabling function are presented as a four-by-four matrix in Table 1.

Table 1. List of the most promising areas for RFID deployment in healthcare (Vilamovska et al., 2009)

	Patient safety/ Quality of care	Pharmaceutical application	Management of devices, supplies and biological material	Patient and healthcare personnel support/ management
Tracking	Tracking vulnerable patients (dementia) Tracking patient location to account for patient time during treatment	Easy recall of products	Prevention of leftins during surgical procedures Equipment tracking (ensure hygiene, compliance, regular maintenance, fast spotting when needed)	Personnel tracking to improve workflow and reduce patient waiting times in emergency room
Identification and authentication	Mother–newborn accurate matching	Auto ID-enabled medication administration system	Maintenance of real-time clinical information associated with patient within a hospital	Patient identification to reduce incidents harmful to patients (wrong drug, dose, time, procedure)
Automatic data collection and transfer	Use of portable devices for care coordination	Tracking pharmaceutical inventories	Inventory management for better use of staff time and faster care delivery	IoT-supported automated care, pathways, procedures audit, and management
Sensing	Patient vital signs to trigger alerts for medical personnel, and remote monitoring at patient's home	Patient compliance with prescribed medication treatment (in and out-patient)	Blood bags equipped with temperature sensors in hospital to ensure cold chain and efficacy	Personnel and asset tracking to ensure infection control (nosocomial infections)

HEALTHCARE DATA ANALYSIS

Healthcare data analysis and analytics can support the basic goals of a healthcare system. The objectives that can be addressed through healthcare data analysis have been classified into three major axes by Cortada, et al. (2012) as presented in the following lines:

- Improvement of clinical effectiveness and patient satisfaction
 - Improvement of clinical quality of care
 - Improvement of patient safety and reduction of medical errors
 - Improvement of wellness, prevention and disease management
 - Better understanding of physician profiles and clinical performance
 - Improvement of patient satisfaction, acquisition and retention
- Improvement of operational effectiveness
 - Reduction of costs and increase in efficiency
 - Optimization of network management
 - Improvement of pay for performance and accountability
 - Increase in operating speed and adaptability
- Improvement of financial and administrative performance
 - Increase in revenue and return on investment (ROI)
 - Improvement of utilization
 - Optimization of supply chain and human capital management
 - Improvement of risk management and regulatory compliance
 - Reduction of fraud and abuse

Data Mining

Data mining emerged in order to cope with the challenges that traditional data analysis techniques were facing up when dealing with large amounts of data. Moreover, these data often have a lot of peculiarities (e.g. missing values, noise, etc.). More specifically, data mining is the main step in the process of Knowl-

Figure 3. The KDD Process. Revised from Tzanis (2012)

edge Discovery in Databases or KDD Process (Figure 3). Knowledge Discovery in Databases is defined as the non-trivial process of identifying valid, novel, potentially useful, and ultimately understandable patterns in data (Fayyad et al., 1996). However, the term “data mining” is very often used to describe the whole KDD Process. Although the core of the process is the data mining step, where a data mining algorithm is applied in order to extract the patterns from data, the pre-processing and post-processing phases are very important too and contribute sensibly to the quality of the extracted knowledge. The pre-processing phase usually includes the selection of an appropriate portion of data, the cleansing of the selected data, as well as the transformation of data in more appropriate representations. The post-processing phase deals with the management of the produced patterns and models and focuses on the evaluation and interpretation of data mining results.

Data mining, in practice, has the following two “high-level” primary goals (Fayyad et al., 1996):

- **Prediction:** Involves the use of some fields (variables) in a database to predict unknown or future values of other variables of interest.
- **Description:** Focuses on finding human-interpretable patterns describing the data.

Prediction and description are not equivalently important for every data mining application. In the context of Knowledge Discovery in Databases, description tends to be more important than prediction. In contrast, machine learning and pattern recognition applications, usually favor prediction as the primary goal. Prediction and description are achieved by using various data mining tasks, the most common of which are presented in Table 2 (Dunham, 2002). Depending on the nature of the data and the desired knowledge there is a large variety of algorithms for each task. A thorough review of the application of data mining in health care can be found in (Koh & Tan, 2005; Yoo et al., 2012).

Table 2. Most common data mining tasks

Tasks for Description	Tasks for Prediction
<i>Association rules mining:</i> Extracts rules expressing relationships among variables of data. Similar task is <i>sequence analysis</i> where relationships are based on time. <i>Clustering:</i> Groups data, so that data in the same group (cluster) are more similar to each other than to those in other groups. <i>Summarization:</i> maps data into subsets with associated simple descriptions. Also called <i>characterization</i> or <i>generalization</i>.	<i>Classification:</i> Maps data into predefined classes, using a model that is constructed on data with known class mappings. <i>Regression:</i> Maps data into a real valued prediction variable, using a model constructed on data with known mappings. <i>Time series analysis:</i> Examines the sequence of events where an event is determined by one or more of the preceding events.

Big Data Challenges

Although data mining provides the means to deal efficiently with large amounts of, usually, peculiar data, healthcare data analysis in the Internet of Things era is far from an uncomplicated task. The term “big data” is very popular nowadays and is used to describe the explosively extended collections of data, which carry significantly more peculiarities. The popularity of the “big data” concept is signified by the fact that a lot of challenges regarding the management and analysis of big data have been raising, whereas the benefits and opportunities ensuing from the exploitation of these data seem to be manifold and very attractive. The conventional data analysis tools, including machine learning and data mining, are not efficient anymore and have to be scaled in order to deal with the obstacles posed by the big data paradigm.

The basic peculiarities that figure the challenging character of big data are described by the “5-V’s”. Laney (2001) introduced the term “3-V’s” in big data community, namely volume, variety, and velocity. However, since then there have been proposed even more “V’s”, but four of them, variability, value, veracity, and visualization are the most popular (Fan & Bifet, 2012). These “7-V’s” are described in the following lines (Dataconomy, 2014; Fan & Bifet, 2012; Fayyad, 2012):

- **Volume:** The volume of the data has been growing rapidly, more than ever before, providing challenges in loading, processing, and transferring.
- **Velocity:** The velocity of data streams that arrive continuously and need to be analyzed pose challenging real-time constraints.
- **Variety:** There are many different types of data (e.g. text, sensor data, images, audio, video, graph), various degrees of structure in data (structured, semi-structured, unstructured), and often different types and structures of data are mixed.
- **Variability:** The structure of the data as well as the way users are willing to interpret these data usually changes with time providing extra data and knowledge management challenges.
- **Value:** The value refers to the quality of the extracted knowledge that may give the ability of making better decisions and answering more questions.
- **Veracity:** Veracity refers to data accuracy, relating to reliability of data source.
- **Visualization:** Visualization refers to how challenging is data visualization.

SOLUTIONS AND RECOMMENDATIONS

Health care, like many other areas, follows the big data paradigm presented above. Healthcare data are becoming available at rapid rates and as the exploitation of the IoT infrastructure grows, data management and data analysis becomes even more challenging. Subsequently, individual hardware units are not any more adequate to satisfy the computational requirements for managing and analyzing these data. New algorithmic approaches with increased scalability and efficiency and infrastructures that make use of the computational power of multiple hardware units, such as distributed and cloud computing, are deemed necessary.

The prevalent trend in dealing with the big data storm is the concept of cloud computing. According to NIST definition (Mell & Grance 2011), “cloud computing is a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources that can be rapidly provisioned and released with minimal management effort or service provider interaction”.

Cloud services can be grouped in three main groups (Mell & Grance 2011):

- **Software as a Service (SaaS):** The capability provided to the consumer is to use the provider’s applications running on a cloud infrastructure. The applications are accessible from various client devices through either a thin client interface, such as a web browser or a program interface.
- **Platform as a Service (PaaS):** The capability provided to the consumer is to deploy onto the cloud infrastructure consumer-created or acquired applications created using programming languages, libraries, services, and tools supported by the provider.
- **Infrastructure as a Service (IaaS):** The capability provided to the consumer is to provision processing, storage, networks, and other fundamental computing resources where the consumer is able to deploy and run arbitrary software, which can include operating systems and applications.

There are various cloud deployment models that have their own benefits and drawbacks. The selection of a proper model depends on the specific application domain. These deployment models are (Mell & Grance 2011; Botta et. al, 2016):

- **Private Cloud:** Provisioned for exclusive use by a single organization and may be owned, managed, and operated by the organization, a third party, or a combination of them.
- **Community Cloud:** Provisioned for exclusive use by a specific community of consumers from organizations that have shared concerns and may be owned, managed, and operated by some of the organizations in the community, a third party, or a combination of them.
- **Public Cloud:** Provisioned for open use by the general public and may be owned, managed, and operated by a business, academic, government organization, or a combination of them.
- **Hybrid Cloud:** Composed of two or more distinct cloud infrastructures (private, community, or public) that remain unique entities, but are bound together by standardized or proprietary technology that enables data and application portability.
- **Virtual Private Cloud:** Exploits virtual private network (VPN) technologies for allowing organizations to setup required network settings (e.g. topology, security, etc.).

Cloud computing and the IoT are two novel and promising concepts of technology that have been evolving independently. Although they are different, they have complementary characteristics as shown in Table 3. Due to this complementarity many researchers have been thinking about the possible benefits of the fusion of these two technologies proposing approaches that integrate cloud computing and the IoT (Cloud-IoT) in various application domains (Alhakbaniet al., 2014; Botta et. al, 2016; Diaz et al., 2016; Gomes et al., 2014). The benefits are mutual for these two technologies. The IoT can exploit the virtually unlimited capabilities and resources of cloud computing to compensate its technological constraints and cloud computing can extend its scope to deal with real world “things” in a more distributed and dynamic manner, delivering novel services in a large number of real life cases.

Table 3. Complementary characteristics of cloud computing and IoT (Botta et. al, 2016)

	Internet of Things	Cloud Computing
Displacement	Pervasive	Centralized
Reachability	Limited	Ubiquitous
Components	Real world “things”	Virtual resources
Computational capabilities	Limited	Virtually unlimited
Role of the Internet	Point of convergence	Means for delivering services
Big data	Source	Means to manage

The adoption of the innovative infrastructures of Cloud computing and IoT in health care has lead to a paradigm shift in healthcare data management and analysis. The traditional standalone, local, offline data analysis model has been replaced by a more dynamic, global and regularly online data management and analysis paradigm. Cloud-IoT is able to simplify healthcare processes, enhance the quality of medical services by enabling cooperation among interconnected entities. For example Ambient Assisted Living (AAL) aims at easing the daily lives of people with disabilities and chronic diseases [Botta et. al, 2016].

Cloud-IoT may supply many innovative services, such as patients' vital data collection through sensor networks, data transfer to medical centers' Cloud infrastructures, management, sharing and ubiquitous access of Electronic Healthcare Records (EHR), etc [Botta et. al, 2016, Kuo, 2011]. Moreover, Cloud allows better confrontation with common challenges of healthcare domain such as security, privacy, and reliability, by enhancing medical data security as well as service availability and redundancy. Cloud enables the execution of secure healthcare services, overcoming the issue of limited computational capacity and power. It provides the means for a flexible and scalable storage and processing in order to efficiently perform online and offline analyses of data.

Another new concept in the area of computing is edge computing that can be thought as an advanced version of Cloud computing (Khan et al., 2019). It brings cloud computing services closer to the end-user and is characterized by fast processing as well as short response time. The common practice is that end-users run fast-processing and quick-response applications on their mobile devices that have limited resources, while basic services and data processing are performed on cloud servers. Using cloud services on mobile devices results in high latency and mobility problems. Edge computing meets the aforementioned application requirements by transferring processing to the edge of the network. Thus, cloud computing issues can be solved through the three edge computing models, Cloudlets, Fog computing and Mobile Edge computing (Khan et al., 2019). However, the complexity of Edge computing systems has given rise to a number of challenges, such as mobility management, security and privacy, scalability, heterogeneity, reliability, and resource management (Khan et al., 2019).

FUTURE RESEARCH DIRECTIONS

The introduction of the Cloud-IoT paradigm in the healthcare domain offers numerous benefits and opportunities that will considerably improve the quality of healthcare services in the era of big data. This is a recently emerged research area and is expected to receive the focus of the future research efforts. Although the aims for storage and management of large amounts of data in the IoT infrastructure can be provided by the integration of the IoT and cloud computing, there are still open issues concerning verification, normalization, filtering and analysis of the IoT data (Diaz et al., 2016). The lack of open standards, the large diversity of technologies involved in the IoT, as well as the huge amounts of data require novel techniques to improve and optimize such integration problems.

From a broader perspective, the basic challenges that concern the IoT healthcare applications using cloud and edge computing services and should be addressed in the future are presented below (Atzori et al., 2010; Botta et. al, 2016; Khan et al., 2019; Rose et al., 2015):

- **User's trust, privacy and security:** These challenges may concern the lack of trust in the cloud and edge computing service providers, the lack of knowledge about the physical location of data, the exposure of the distributed system to possible attacks and vulnerabilities, etc.
- **Legal and Social Issues:** The legal challenges are important depending on the specific application and different international laws. Moreover, social issues become extremely important, since humans are becoming the source of sensor data.
- **Large Scale:** This relates to applications which include a very large number of "things", distributed across very wide areas.

- **Reliability and fault tolerance:** This arises with mission-critical applications. Machine learning algorithms for anomaly detection and predictive maintenance are deemed important in order to deal with these problems.
- **Performance:** This concerns applications having specific performance and Quality of Service requirements at multiple levels (communication, computation, storage).
- **Heterogeneity:** This refers to heterogeneity of devices, platforms, operating systems, services, etc.

An emerging trend in the area of IoT is “intelligent connectivity”, which represents the fusion of IoT, Artificial Intelligence and 5G networks promises to provide new transformational capabilities. As defined by GSMA (2018), “Intelligent Connectivity” is the term used to describe “the powerful combination of flexible, high-speed 5G networks, the Internet of Things and Artificial Intelligence. Underpinned by ubiquitous, hyper connectivity, intelligent connectivity marks the beginning of a new era defined by highly contextualised and personalised experiences, delivered as and when one wants them. It will have a significant and positive impact on individuals, industries, society and the economy, transforming how we live and work”.

Given the capabilities of 5G networks, users will be able to wear connected wellness and safety devices that provide ongoing information on their location, vital signs, and other parameters. Emergencies such as falls or catastrophic events can be identified. This information enables individuals to track their specific needs in order to benefit from personalized prevention and predictive healthcare programs, as well as personalized health insurance and safety solutions. As for the healthcare sector, continuous connectivity will enable better management of resources and will ensure that clinics are not run out of equipment and critical medicines. Nowadays, medical expertise is still largely restricted to the location of the physician. However, the advent of tactile Internet will allow the physical examination to be carried out remotely anywhere and at any time, without restrictions (GSMA, 2018).

CONCLUSION

Undoubtedly the IoT is the future of technology, which can provide manifold benefits to health care. However, the posed challenges are also great. Concerning the analysis of healthcare data, various tools have been introduced to deal efficiently with the large volumes as well as the various peculiarities of data (e.g. missing values, noise, etc.). The most popular representative of these modern tools is data mining, or the KDD process, strictly speaking. Although the KDD process has provided a lot of solutions, these techniques have to be scaled in order to deal with the new challenges posed by the big data paradigm. Cloud computing is the modern infrastructure that can provide the means to efficiently manage big data. Both, cloud computing and the IoT are very promising concepts of technology and their complementary characteristics assure that their integration, Cloud-IoT, provides a great potential of applications. The introduction of the Cloud-IoT paradigm in the healthcare domain can offer manifold benefits and opportunities that will considerably improve the quality of health care. The newly emerged area of edge computing complements cloud computing and brings cloud services closer to the end-user and providing faster processing as well as short response times.

KEY TERMS AND DEFINITIONS

Ambient Intelligence: The discipline aims to bring intelligence to everyday environments making them sensitive and responsive to the presence of people in a non-intrusive way and with minimal explicit interaction.

Artificial Intelligence: The area of computer science that studies the construction of computer programs that can imitate human cognitive abilities and present behaviors indistinguishable from human behavior.

Internet of Everything (IoE): A broad term that is used to describe a superset of Internet of Things which includes all sorts of things and connections that one could imagine.

Internet of Medical Things (IoMT): A global infrastructure consisting of the collection of medical devices and applications that are interconnected through information and communication technologies.

Machine Learning: The field of study that deals with the construction of algorithms that can learn from data and make predictions on data.

Radio Frequency Identification (RFID): The technology that incorporates the use of electromagnetic fields to uniquely identify and track a tagged object.

Tactile Internet: The Internet that combines extremely low latency with very high availability, reliability, and security.

Ubiquitous Computing: The discipline aims to bring computing anywhere and anytime in any object. It is also called pervasive computing.

Wi-Fi: The technology that allows electronic devices to connect to a wireless local area network (WLAN) and Internet using radio waves.

Wireless Sensor Network (WSN): The network of spatially distributed autonomous sensors which monitor physical or environmental conditions and cooperatively pass their data through the network to a main location.

Internet of Things in Healthcare as an Innovative Form of Personalized Medicine

INTRODUCTION

According to the US National Intelligence Council, there are six technologies with potential impacts on the US interests out to 2025 (the US National Intelligence Council, 2009): Biogerontechnology; Energy Storage Materials; Biofuels and Bio-based Chemicals; Clean Coal Technologies; Service Robotics; Internet of things.

The great potential offered by the Internet of Things technology enables their wide applications in many areas of society, which would significantly increase and improve the quality of their functioning. By equipping various environments, i.e. domains, even with devices with primitive intelligence and modest communication capabilities, the communication of these entities with each other would be possible, with an aim to ensure data management. Such systems can be widely used in the following areas: Healthcare Domain; Smart Environment Domain; Personal and Social Domain; Transport and Logistics.

BACKGROUND

The Internet of Things (IoT) refers to wireless networks between objects (things). ‘Things’, i.e. objects, become entities with virtual properties which operate and communicate in smart spaces using intelligent interfaces.

Also, the “Internet of Things” is the general idea of things, especially everyday objects that are readable, recognizable, locatable, addressable, and controllable via the Internet - either via Radio Frequency Identification (RFID), Bluetooth, Wi-Fi, telephonic data services, wide-area network, or other means (the US National Intelligence Council, 2009).

In their research paper, Atzori et al. (2010) state that the Internet of Things can be realized in three paradigms: internet-oriented (middleware), things-oriented (sensors) and semantic-oriented (knowledge).

Over the last 20 years, continuous changes in the healthcare domain have taken place, caused by the wide use of information and communication technologies in the medical field. IoT plays a significant role in the broad range of healthcare applications which could be grouped as follows (Atzori et al. (2010)):

- Tracking of Objects and People (Staff and Patients);
- Identification and Authentication of People;
- Automatic Data Collection and Sensing.

DOI: 10.4018/978-1-7998-3479-3.ch134

The rapid growth of IoT has resulted in a massive growth of data generated by these devices and sensors put on the Internet. The physical-cyber-social big data consist of these IoT data, complemented by the relevant Web-based and social data (Sheth, 2016).

The Internet of Things has been identified as one of the emerging technologies in the IT field. The market adoption of IoT has been forecast to take 5–10 years (Gubbi et al. (2013)).

The Internet of Things (IoT) is a platform and a new paradigm for interconnecting electronic devices i.e. global communication among millions of electronic devices connected to the internet.

Personalized healthcare systems deliver e-health services to fulfill the medical and assistive needs of the aging population. Internet of Things is a significant advancement in the Big Data era, which supports many real-time engineering applications through enhanced services. (Jagadeeswari et al. (2018), Khan et al. (2018)).

E-health in Serbia has been the subject of some studies. It was concluded that information and communication technologies are rarely implemented (Milenkovic et al. (2012)).

IoT is a vision which refers to the humanization of technology.

IoT IN HEALTHCARE DOMAIN

Medical sensors are devices that measure a number of physical, chemical, or biological parameters and then transmit or report these data. Some sensors are designed to work outside the body, and others are implanted in the body.

In the healthcare domain, the Internet of Things in its essence covers the following (Li et al. (2009)):

- Body Area Network (BAN): the thermometers, smart t-shirts, smart devices and sensors for health, paper-based home pregnancy tests, etc. supporting personal medical treatment and healthcare.
- Wireless Body Area Network (WBAN): supporting remote medical treatment and healthcare.
- Local Area Network (LAN): the wireless access-based remote patient monitoring system, the smart devices as a hospital interface, pulse oximeter also known as the blood-oxygen monitor, etc.
- Wide Area Network (WAN): telemedicine solutions, distance medicine, etc.
- Very Wide Area Network (VWAN): the smart healthcare solutions as e-health services everywhere, no longer tied to physical locations.

Tracking involves memorizing the positions in real time (e.g. patient flow monitoring) in order to improve work processes in hospitals, but can also refer to the general tracking of motion (e.g. the access to certain rooms, warehouses or inventory material tracking such as blood samples and other materials necessary for the hospital functioning). Identification of patients includes activities, actions and tasks aimed at reducing incidents harmful to patients (e.g. wrong drug, dose, time, and procedures), the maintenance and updating of the complete medical archives in the digital form. Identification and authentication include protocols and procedures regarding the work of medical staff, which promotes morals and ethics of employees in order to increase patient safety. The automatic data collection and transfer involves the automation of various processes as well as the management of medical supplies. This function is supported by the integration of the Radio Frequency Identification (RFID) technology and other health information and technologies. RFID is a method of storing and downloading data remotely, using devices carrying tags. From the RFID group's point of view, the Internet of Things is the worldwide network of interconnected objects uniquely addressable based on the standard communication protocols

(Gubbi et al. (2013)). Sensor devices allow more successful diagnosis of patients in real time; provide various solutions in the field of telemedicine, warnings about the patient's condition and so on. They offer numerous opportunities that would provide, for example, a wireless access-based remote patient monitoring system, which would be designed so as to accompany the patient everywhere in real time, thus enabling continuous monitoring of the patient's bio-signals (Niyato et al. (2009)).

CONCEPT OF M-HEALTH

As mobile technology becomes more affordable and widespread all over the world, using the mobile-enabled technology when providing healthcare services has great potential to improve the health of millions.

Mobile Health, mHealth is a term used for medical and public health practice supported by mobile devices, such as mobile phones, patient monitoring devices, etc.

MHealth is a relatively new concept, but its main advantage is that it enables healthcare professionals to collect data about their patients at any time. The data is processed, analyzed and wirelessly communicated to a gateway device over a cloud. (Paschou et al. (2013), Paschou et al. (2015), Istepanian et al. (2004)).

Considering that MHealth, as a part of eHealth, can be defined as the synergistic solution of mobile computing, a medical sensor, and communications healthcare technologies, whose common goal is wireless monitoring of the psycho-physical state of health or remote patient monitoring. In the Republic of Serbia, electronic health cards are a pioneering venture aimed at promoting mobile healthcare services (Milenkovic et al. (2012)).

An MHealth solution usually consists of a unit designed for patients, which is composed of sensors for medical measurements and accessories, as well as a communication device for 2G and 3G communication, which forwards the data to the health system via cloud. Because of their miniature dimensions, high performance and low cost/price, different sensors, which can be easily wirelessly connected, are used for the measurement of chemical, biological and physical parameters in the body. Also, there are a lot of web-based platforms that provide additional opportunities for the expansion of social networks for different purposes (e.g. health education of patients worldwide). Even more, the network of sensors can be connected via patient's mobile phone to a server that is located in a medical institution. The data collected by the sensor network can be periodically or in real time sent to the server, which approaches the patient's doctor suggesting corrective actions via e-mail or SMS. The program can be set so as to, if the sensor encounters some irregularities, immediately notify a doctor, who could react momentarily.

Thanks to this approach, patients with chronic diseases can be under continuous remote supervision at home. In addition to the increased safety of the patient, it represents significant savings of hospital resources, and hospital beds remain available for other patients who need them. Also, this solution helps hospitals manage beds efficiently and consequently decreases hospital costs. Hospitalized patients whose health status requires full attention can be constantly monitored using IoT-driven monitoring (sensors).

The market division is as follows:

- Preventive care tools which help people stay healthy (e.g. Behavioral change, Community communication, Education).
- Curative care tools as new efficient ways to treat patients (e.g. Remote monitoring, Assisted living, Tele-consultations).
- Productivity tools which improve efficiency and availability (e.g. Electronic health records, Professional communication).

TELEHEALTH

Telehealth (telemedicine) is a health delivery system which refers to the exchange of medical information between two sites via electronic communications in order to improve a patient's health status. Telehealth includes a growing range of applications and services using two-way video telephony, wireless tools and networks, emails, smart devices, Internet and cloud services and infrastructures, and other forms of telecommunications technology. Clinical telemedicine practice supported by video conferencing, medical connectivity through m-health, remote patient monitoring, disease management, home healthcare, continuing medical education, medical call centers, are all considered part of telemedicine and telehealth. Health professionals providing telehealth services should have the continuing education, training, licensure, in order to acquire the necessary knowledge and competencies needed to provide safe and high-quality telehealth services.

From 2013 to 2020 the telehealth market's compound annual growth rate is expected to be around 46 percent. The digital health market is expected to reach 233.3 billion US dollars by 2020. The telemedicine market has grown significantly in recent years. As of 2015 the telemedicine global market was valued at some 18 billion U.S. dollars. The market is expected to grow significantly by 2021 and is expected to be valued at more than 41 billion U.S. dollars at that time. The statistic shows the projected growth of the total number of telehealth patients worldwide from 2013 to 2018. Also, a statistic show the estimated number of mHealth app downloads worldwide from 2013 to 2017, in billions of downloads. It is estimated that in 2017 there will be 3.7 billion mobile health app downloads (Statistic (n.d.)).

How telepsychiatry expands access to care? In February 2018, American Psychiatric Association (APA) updated its Policy on Telepsychiatry: "Telemedicine in psychiatry, using video conferencing, is a validated and effective practice of medicine that increases access to care. The American Psychiatric Association supports the use of telemedicine as a legitimate component of a mental health delivery system to the extent that its use is for the benefit of the patient, protects patient autonomy, confidentiality, and privacy; and when used consistent with American Psychiatric Association policies on medical ethics and applicable governing law." (Telepsychiatry. (n.d.))

With the "anytime, anywhere framework," telepsychiatry is changing the way communities and the medicine as a whole approach mental and behavioral healthcare.

Telepsychiatry delivered via videoconferencing technology allows patients to connect with providers remotely from their home or other private place where they are located.

By increasing access to care and real time support with qualified professionals who can quickly and effectively assess situations, with a proactive intervention that minimizes the potential for escalation, telepsychiatry is becoming an important strategy in the future in preventing the mental health crisis.

Telepsychiatry helps to avoid unnecessarily transferring patients to a hospital by instantly connecting to behavioral health specialists to assess and determine the best treatment plan.

Telepsychiatry plays an important role as a solution that eliminating unnecessary hospitalization, opens up a new approach to mental illness, and empowers timely and more effective mental and behavioral healthcare.

TECHNICAL REQUIREMENTS FOR REAL-TIME INTERACTIVE SESSIONS

The quality of a video healthcare interactive session primarily depends on the characteristics of the network connection between the conferencing sites. The H.323 standard specifies the components, pro-

protocols, and procedures for the transmission of real-time audio, video, and data communications over IP (Internet Protocol), i.e. packet-based, networks. In the case of H.323, a high-quality conference, which implies excellent audio and video, needs from 768 kbps (kilobits/second) to 2 Mbps (megabits/second) in each of the downlinks and uplink directions.

In the case of “Point to point video conferencing”, two H.323 video conferencing systems communicate to each other over the Internet. One station initiates the call, and the other either accepts or rejects it. Once accepted, encoded and compressed audio and video flow between the two stations. In the case of “Multipoint video conferencing” more than two sites communicate with each other. In the H.320/ISDN world, a Multipoint Control Unit (MCU) was used. This allowed three or more user stations to connect to the MCU. In the case of the voice switching mode, the MCU made a decision about which site was currently talking. Smartphones and tablets (such as iPhones and iPads) do support live conferences; however, 3G/4G/LTE/WiFi connections are not sufficiently reliable for participating in online sessions. It is highly recommended to use a computer with a wired internet connection. In the case of high-quality (HQ) resolution, 640x360@15, 30 fps (frame per second) is recommended, but in the case of full High Definition resolution (FHD), 1920x1080 30 fps is recommended. Graphical cards must be compatible with DirectX 10.0, from 512MB (min. NVidia 8600 GS, Radeon HD 2600 XT, Intel HD Graphics 2000) to 2GB (min. NVidia GT640, AMD Radeon HD 6670, Intel HD Graphics 4000).

Minimum system requirements for conference hosts are: Windows XP 32 bit or Windows 7 (32bit or 64bit); Core2 Quad, Intel i3, i5 or i7 equivalent CPU; 4 GB of RAM; 100 MB of available HDD space (additional space recommended for conference recording features); 100 MB NIC or higher; High speed broadband Internet access (at least 1 Mbps upstream and 4 Mbps downstream); DirectX 9.1 or later compatible webcam; DirectSound compatible audio input and headset or speakers (Video Conferencing System Requirements (n.d.), Web & Multiparty Video Conferencing System Requirements (n.d.), VCI - Next Generation Video Conferencing (n.d.)).

The video conference software should be able to adapt to changing bandwidth environments without losing the connection. Health organizations should have the appropriate redundant systems in a place that ensures availability of the data transmission infrastructure for critical connectivity.

DIGITAL TRANSFORMATIONS IN MEDICINE

mHealth has the potential for use in the following areas:

- Education and training of healthcare workers;
- Remote data collection and remote monitoring;
- Remote diagnostic and treatment support.

Today's healthcare consumers are more motivated than ever before to take action for better health. In response, healthcare organizations from hospitals to large health systems, are seeking methods to ensure new tactics to meet the core strategic need of the healthcare industry: a higher value of care at a lower cost. As such, three key trends are developing as consumerism takes hold in healthcare. Key learning objectives: (i) Leveraging data from consumer health technologies to better engage patients; (ii) Creating a provider-patient dialogue utilizing patient-generated health data; (iii) The value of deploying enterprise platform solutions for care management (Validic. (n.d.)).

The main advantages brought by the concept of mHealth imply the increase in the quality of health care, while creating new opportunities on the one hand, and reduced costs on the other hand. About 75% of patients suffer from chronic diseases (high blood pressure, diabetes, heart disease, cancer, etc.). Using mHealth solutions, the biomarkers of these chronic patients can be monitored ensuring the quality management of their diseases in order to improve the quality of their life. These technologies exist and have been adopted, and their examples are: the wireless Helder monitors, weight scales, blood pressure cuffs and glucometers (Malvey et al. (2014)).

In order to be cost-effective and commercially-sustainable for the mass-market, mobile health services should be standardized. One of the problems is that today there is not an organization in the world which deals with the standards in the field of mHealth. For example, the International Standards Organization (ISO) has developed standards (IEEE 11073) for the transmission of blood pressure in a basic binary data format between two low-level devices, which can be transferred into a human-readable format using health messaging standards, such as HL7 (Engineering in Medicine and Biology Society (n.d.)).

Some of the mHealth categories (Applications and Devices) are: Nutrition Application, Glucometers, Biometrics devices, Sleep Trackers Applications and devices, Tobacco Cessation Applications and Programs, Medication Adherence Devices and so on (Validic. (n.d.)).

Some examples of the use of medical sensors are as follows: the sensors can help detect, and thus avoid, about 5000.00 known viruses that cause serious illness around the world. Biochemical sensors can continuously scan a billion miles long chain of Deoxyribonucleic acid (DNA) and look for changes and potential diseases. Taking into account the fact that the human heart throughout a life pumps about 15 million gallons of blood, cardiac sensors or heart rhythm sensors can provide information about how efficiently a heart works. The human brain has about 100 billion neurons. Gum sensors have the preventive effect on the development of other diseases in the organism because people who suffer from a gum disease represent 50% of those who are predisposed to suffer brain and heart attacks. New sensors can detect a high level of blood sugar without drawing blood. By using an ultra-sensitive sensor to detect the presence of tumors and early abnormal cell growth, cancer can be recognized at an early stage and thus effectively treated. Biosensors may provide insights into disease processes that are hard to detect directly, such as dysfunctions in brain chemistry that are thought to play an important role in many mental disorders (Health Sensing Infographic, (2014), Sensors. (n.d.)).

The next generation of IoT quantified tracking devices falls into the category of wearable electronics and multi-sensor platforms. These products include smart watches, wristband sensors, wearable sensor patches, artificial reality-augmented glasses, brain-computer interfaces, wearable body metric textiles.

Other important categories include smart phone applications and their enhancements, and environmental monitoring and home automation sensors.

For example, Hexoskin products give insight into the physical training, sleep, and personal daily activities:

- Track heart rate and view real-time ECG with great precision.
- Heart rate variability (HRV) is an essential tool to measure stress and training fatigue to avoid overtraining.
- Breathing rate in order to control own breathing, increase performance and reduce stress.
- Breathing volume in order to control lung capacity for each of daily activities and avoid hyperventilation and apnea.
- Sleep tracking device in order to measure resting heart rate, breathing, and sleep positions.

How could smart pills be innovating health care?

Health care providers are faced with inconsistent and irregular intake of drugs, especially in patients with chronic diseases. With the new phone applications, alarms, smart packaging and IoT innovations such as “smart pill”, the problem of regular patient medication can be improved.

The wireless health technology is beginning with smart pill technologies, also known as “ingestible”, which could change the way of taking the therapy. Key benefits include maximizing drug effectiveness and reducing medical costs due to improper drug usage.

A pill is considered “smart” if it has technological components such as microchips, cameras or sensors that communicate wirelessly with wearable software or mobile applications, on dislocated computers in medical offices, as well as with smart devices.

A smart pill, also known as digital pill, has a drug and an ingestible sensor. The sensor is activated when it comes into contact with stomach fluid to detect when the pill has been taken. The data is then transmitted to a wearable sensor patch which may possibly be transmitted the information to a paired smartphone application. Health care providers, with the patient’s consent, can then access the data via a web portal.

Further expansion of support for digital medicines into the oncology treatment area is not only important for patients and service providers; it will be going in the direction of change in the pharmaceutical industry developing therapies intended to one day eradicate cancer. For example, data gathered from digital oral oncolytic will enable cancer drugs and treatment regimens to be optimized to work their best for each individual patient, something not possible until now. The mechanism which turns data into predictive knowledge as a part of artificial intelligence could help healthcare professionals better understand a person’s health and could have a significant impact on improving quality of life and well-being (Proteus Trends (n.d.)).

In a world where everything is becoming connected, the development of this small piece of technology that can communicate in the field of human health and share information about a patient’s condition with health care providers has received a lot of scientific attention.

It should be kept in mind that these new technologies bring new dangers. Such devices, like all computers, can be hacked or can be broken. Questions about who should control these devices in the body and how they might be turned off are also very important. The advent of these digital pills brings many of ethical quandaries. These drugs and devices hold implications for transforming the clinician-patient relationship, patient trust, patient monitoring, clinical management, and risk management. As these medical technologies become more widespread, manufacturers and providers of health services will need to develop mechanisms to maximize patient benefits and minimize the risks.

FUTURE RESEARCH DIRECTIONS

Generally, the next Internet revolution will be the interconnection between everyday existing objects in order to create a smart grid and intelligent environment. The future application of technology in health care will lead to the creation of an entirely new level of personalized, digital health care, where everyone is responsible for monitoring their own health and the quality of their own life. Further research is aimed at improving the existing sensors through increasing their capabilities and enhancing their efficiency. In the coming period, IoT is expected to play the key roles in all the aspects of modern medical treatment and health management - prevention, diagnosis, disease monitoring, treatment monitoring. This paper emphasizes the growing needs for better functioning of healthcare systems in real-time as well as the

future development of personalized medicine. This innovative technology in the future offers new opportunities for patients, including improvements in lifestyle of patients, and new opportunities for health systems, including reduction of healthcare costs.

From the academic perspective, technological research in data science, machine learning and artificial intelligence will continue to grow. At the social level, we have to consider many ethical issues concerning privacy policy, authority and autonomy that intelligent devices will have.

CONCLUSION

The advances in science, technology, engineering, and medicine will enable the use of sophisticated sensor technologies in the further medical research that could dramatically improve the quality of life of people with serious disabilities as well as in the field of preventive medicine. We can conclude that the technological advancement in the healthcare area revolves around the following outcomes: improved access to care, increased care quality and reduced care costs. The business models behind IoT have been established around the principles of cloud-assisted IoT, where devices collect data that is then transmitted to cloud services. There is, of course, the major issue of ethical use and distribution of sensitive data, which applies to the whole digital world but is especially important in IoT healthcare systems. The Internet of Things is potentially disruptive because global society, global economy and governments are unprepared for a possible future when the Internet nodes will be able to remotely control, locate, and monitor everyday things. Having in mind that everyday objects become information security risks, the IoT could distribute those risks far more widely than the Internet has to date.

Also, based on today's technology, there is simply not enough wireless spectrums to connect trillions of IoT. At this point, the issue of generating and distributing a sufficient amount of energy for the operation of all IOT devices is unresolved, as well as the problem of storing and processing huge amounts of IoT data. To solve these issues, new scientific discoveries are required, especially in low-power communications, energy saving, process optimizations and distributed machine learning.

KEY TERMS AND DEFINITIONS

Body-Area Network: A network that can collect information about an individual's health, fitness, and energy expenditure.

Health Informatics (Healthcare Information Systems): Software solutions for appointment scheduling, patients' data management, work schedule management and other administrative tasks regarding health.

Healthcare Monitoring: The medical applications can be of two types: wearable and implanted. Wearable devices are used on the body surface of a human or just at a close proximity of the user. The implantable medical devices are those that are inserted into the human body.

Internet of Things (IoT): A new concept that has emerged thanks to the development of new technologies, especially the Internet Technologies and Wireless Sensor Networks that together enable the existence of the health system at the global level.

Mobile Health (mHealth): A collection of mobile technologies as tools and platforms for health research and healthcare provision.

Sensor Network: A network that consists of multiple detection stations called sensor nodes, each of which is small, lightweight, and portable.

Sensor Node: A node in a sensor network that is capable of performing some processing, gathering of sensory information and communicating with other nodes connected in the network. The main components of a sensor node are a microcontroller, transceiver, external memory, power source and one or more sensors.

Telemedicine: A physical and psychological diagnosis and treatment at a distance, including tele-monitoring of patients' functions.

Wireless Sensor Networks (WSN): A network that consists of spatially distributed autonomous sensors used to monitor physical or environmental conditions, and to forward their data jointly to the main location through the network.

Highly Aged and After Cloud

Shigeki Sugiyama

 <https://orcid.org/0000-0003-3764-4160>

Independent Researcher, Japan

INTRODUCTION

There have been living more and more highly aged people (after 75 years old). And the number of those highly aged people has been increasing year by year in Japan (JILI, 2019). This might be also a global phenomenon. At this age, some of the tissues and the organs of human will seem to start functioning not perfectly well (Yomeishu, 2012. Tentouyobounavi, 2017). And they will seem to be fragile by all kinds of inside and outside stresses. In another words, it seems that some kinds of phase state changes of the human body will make themselves physically weak. However, it is also known the following things too;

1. A bit of mental assistance will make them work fairly good again.
2. A little bit of physical help will be possibly to make them work very good again. So that, one will not need another's help (including a doctor's help) any more.
3. Just a bit of rest will make the physical body and the mental damage work well again.
4. A novice medical treatment will make the physical body work well again.
5. Just a bit of massage and tapping will make the physical body and the mental damage work again.
6. Etc.

So, in this chapter, it will be studied what sort of things can be done for highly aged people by the help of present high technology of "Cloud". What is more, it will be considered whether "Cloud" is only the technology for helping and assisting the highly aged people or not? Namely, human will understand a thing better if there is an assistance visually and intimately. In this sense, the following technologies are also considered for the usages; Individual Cloud, Fog Computing, AI (Artificial Intelligence), VR (Virtual Reality), and AR (Augmented Reality).

The studies and the arguments will go on under the following steps.

1. Firstly, it will be considered what sort of physical body and mental damages will come out to the highly aged people.
2. Secondly, it will be studied what sort of assistance and help will be needed for those damages.
3. Thirdly, it will be studied what sort of assistance and help will be possible to use the present technologies; Cloud, Individual Cloud, Fog Computing, AI, VR, and AR.
4. Finally, conclusion.

MAIN FOCUS OF THE CHAPTER

16

Problems with Highly Aged So Far

Strange to say that bodily weakness will start being recognized around from the age of 75 years old to 80 years old by themselves. Legs, wrist, hands, arms, shoulder, neck, and brain will be the parts of weakened. At a glance, it seems that every bodily movement is not smooth, not in harmony, not in strength, not in active, and not in vivid. And it seems that the joints will be easily twisted, hurt, and broken. And it seems that a brain is not functioning as fast (quickly) as the decades ago. In another words, the brain responses slowly or very faintly to a stimulation. These problems will have a bad influence in a daily life to those people, which will sometimes cause a difficulty in the livings and a life.

So, as the summary of these problems mentioned above, they may be rewritten and categorized again as follows.

1. Physical Matters:

/A physical body will naturally start being weakened from around 75-80 years old.

/This phenomenon will be going further worse gradually, or seldomly it will happen suddenly. / Sometimes it will get worse and worse after the weakened.

What is more, the physical matters will be further divided into functional parts.

- a. The bones related parts.
- b. The muscles related parts.
- c. The internal organs related parts.

2. Mental Matters:

/A brain will naturally start being weakened from around 75-80 years old.

/This phenomenon will be going further worse gradually, or it will sometimes happen suddenly.

/Sometimes the one will be lost.

What is more, the mental matters will be further divided into functional parts.

- a. All over the brain (Frontal lobe, Parietal lobe, Occipital lobe, and Temporal lobe). It may seem that Temporal lobe and then Frontal lobe will be likely firstly weakened and damaged.
- b. Brain Part Focused.

Frontal lobe, Parietal lobe, Occipital lobe, and Temporal lobe.

Computer Assistance and Help

There are many kinds of AI usages in almost every field. AI is quite often used for control, an intelligent control, an intelligent system, deep learning, Cloud, a knowledge base, data base, management, a production system, statistics, sales force, environment examination, agriculture, art, livings, daily life, etc. Those usages are helpful, useful, and reliable. Because the outputs come up to us soon after commands are input by manual or by voice. And the output results will be used for practical usages of jobs, daily

life, entertainment, research, and many others. Under these situations, here looks at what the computer assistance would be able to do for the highly aged people.

In a case of Cloud, it has the following background. And those related things are already come up to the real world in a real usage.

The word of “Cloud” has come to this world many decades ago from a workstation computer company researcher. Since then, the time has passed for some decades without being paid any attention by researchers and engineers in the world. But the end of 20th century, “Cloud” comes up to this world suddenly again without any notice. Since then, Cloud related hardware and software have been fulfilled so much and so many in this world. But they are not friendly to users at all at first stage. Because the systems and the many kinds of software are not user friendly at all at the first stage. They seemed only to give a software wanted to a user platform remotely. And there are any data shares for each software. However, as the first stage, Cloud gave a good and nice impression to most of the users. Some of them are as follows (Sugiyama, 2019);

1. SAP: (Enterprise Resource Planning)
2. SOA: Service Oriented Architecture
3. SaaS: Software as a Service
4. Mash UP: Mashing Up software
5. Meta Frame: (peer to peer relation)
6. PaaS: Platform as a Service
7. HaaS: Hardware as a Service
8. IaaS: Infrastructure as a Service
9. Cloud: Cloud Computing within a particular area
10. Mini Cloud: Various Kinds of Small Cloud
11. Individual Cloud: Purposely Made Cloud for Individual
12. Fog Computing (Cloud): Internet Of Things (IoT) in Cloud
13. AI and Cloud: at present
14. VR, AR, AI, and Cloud: the coming near future

Those systems and functions mentioned above may have been generally concluded as a part of “Cloud” Computing mainly to solve problems at a company, an individual, a community, a system, a handicapped, and a society.

Nowadays, “Cloud” has become more user friendly. And as broad ways of usages, they have been offered from “Cloud” in/of a mainframe to Desktop’s, to Laptop’s, and to Smart Phone’s.

At this stage of the technologies flow, it would not be rough and over expected idea that Cloud (and Individual Cloud, Fog Computing, AI, VR, and AR) is a necessary and an important concept of the assistance and the help for highly aged people (Sugiyama, 2012. Sugiyama, 2013a. Sugiyama, 2013b. Sugiyama, 2018. Sugiyama, 2019).

SOLUTIONS AND RECOMMENDATIONS

Transform and Strengthen Weakness To Normal

As mentioned in the above section, there are two categories for assisting and helping the highly aged people, namely the physical and the mental assistance and help. In order to do these things, it is important to comprehend the vital situations (the physical matters and the mental matters) of the highly aged people.

The problems are described here again. And here studies how to transform Weakness to Normal, and to strengthen Weakness to Normal.

1. Physical Matters:

/A physical body will naturally start being weakened from around 75-80 years old.

/This phenomenon will be going further worse gradually, or seldomly it will happen suddenly. / Sometimes it will get worse and worse after the weakened.

What is more, the physical matters will be further divided into functional parts.

a. The bones related parts:

This is again divided into two. Namely, one is Prevention and the other is Medical Treatment.

i. Prevention:

There are lots of information on the medical attentions on the prevention of the bones related parts. It will be possible to use them in a daily life for the highly aged people. It can be offered by using “Cloud” and “Individual Cloud”. What the highly aged people are now doing can be predicted by the iPhone with them (necessary information: the place, the surroundings, etc.) through “Fog Computing”. By using these data, “Cloud” and “Individual Cloud” can tell the highly aged people through their iPhones about the accidents’ possibilities that will be occurring. In addition to these, it will be possible to check whether they are doing those preventions or not. What is more, these preventions in the medical attentions will be able to be offered by VR and AR through the iPhone with them. VR can offer the necessary information visually to the highly aged target people in detail or in roughly as wanted. AR can offer the necessary information virtually mixed with the reality around the highly aged target people as wanted. These matters are now possible with the present IT; Cloud, Individual Cloud, Fog Computing, AI, VR, and AR.

ii Medical Treatment:

It will be possible to offer the medical treatment information to the highly aged people. It can be offered by through “Cloud” ® “Fog Computing” ® “Individual Cloud” ® The highly aged people (¬ “Individual Cloud; The related kind of Hospitals, the Nurses, and the Medical Managers” ¬ “Cloud”).

b. The muscles related parts:

This is again divided into two. Namely, one is Prevention and another is Medical Treatment.

i Prevention:

There are lots of information on the medical attentions on the prevention of the muscles related parts. It will be possible to use them in a daily life for the highly aged people. It can be offered by using “Cloud”. What the highly aged people are doing can be predicted by the cellular phone with them (necessary information: the place, the surroundings, etc.) through “Fog Computing”. By using these data, Cloud is able to tell the highly aged people through their cellular phones about the accidents possibilities that will be occurring. In addition to these, it will be possible to check whether or not they are doing those preventions. After all, these matters are now possible with the present IT; Cloud, Individual Cloud, Fog Computing, AI, VR, and AR.

ii Medical Treatment:

It will be possible to offer the medical treatment information to the highly aged people. It can be offered by through “Cloud” ® “Fog Computing” ® “Individual Cloud” ® The highly aged people (→ The related kind of Hospitals, the Nurses, and the Medical Managers).

After all, these matters are now possible with the present IT; Cloud, Individual Cloud, Fog Computing, AI, VR, and AR. Especially, AI, VR, and AR will role an important play for the medical treatment.

c. The internal organs:

The internal organs are able to be sensed by using the technology and the study of MEMS (Micro Electro Mechanical Systems). These are still under research and development works, but it is very important to get them in order to put them into the circulation of “Individual Cloud” ® “Cloud” ® “Individual Cloud” ® “Fog Computing” ® The highly aged people for the medical treatment.

In the same way as mentioned in the above sections, “Prevention” and “Medical Treatment” will be done by using the technologies of IT; Cloud, Individual Cloud, Fog Computing, AI, VR, and AR.

2. Mental Matters:

/A brain will naturally start being weakened from around 75-80 years old.

/This phenomenon will be going further worse gradually, and or it will happen suddenly.

What is more, the mental matters may be further divided into functional parts.

a. These things will be related with all over the brain (Frontal lobe, Parietal lobe, Occipital lobe, and Temporal lobe):

It may be said that Frontal lobe and Temporal lobe will be likely firstly damaged. These are still under research works and technological developments, but it is very important to get them in order to put them into the circulation of “Individual Cloud” ® “Cloud” ® “Individual Cloud” ® “Fog Computing” ® The highly aged people for the mental matters’ enlightenment treatment.

In the same way as mentioned in the above sections, “Prevention” and “Medical Treatment” will be assisted by using the technologies of IT; Cloud, Individual Cloud, Fog Computing, AI, VR, and AR. In this case, it will be very difficult to understand the situation of oneself in detail. Because the behavior of the one cannot be accurately grasped. So, Individual Cloud would play the most important role.

b. Frontal lobe (Prefrontal cortex):

The prefrontal cortex is the place where “the entity” as “human” can be determined by the groups of neuron activities. This is the place where a consciousness and a consciousness state come out. And this is the place where many abstracted matters like “love”, “desire”, “feeling”, “mind”, etc. come out in a consciousness and a consciousness state. Namely, this is the most important place and part in the brain as a humankind. These are still under research works and technological developments, but it is very important to get them in order to put them into the circulation of “Individual Cloud” ® “Cloud” ® “Individual Cloud” ® “Fog Computing” ® The highly aged people for the mental matters’ enlightenment treatment.

In the same way as mentioned in the above sections, “Prevention” and “Medical Treatment” will be assisted by using the technologies of IT; Cloud, Individual Cloud, Fog Computing, AI, VR, and AR.

In the same way as mentioned in the above sections, “Prevention” and “Medical Treatment” will be assisted by using the technologies of IT; Cloud, Individual Cloud, Fog Computing, AI, VR, and AR. In this case, it will be very difficult to understand the situation of oneself in detail. Because the behavior of the one cannot be accurately grasped. So, Individual Cloud would play the most important role.

FUTURE RESEARCH DIRECTIONS

This area is just started to study and to research.

The physical and mental situations of the highly aged people are not the same individually as known quite well. And so, it is not an easy matter to understand the directions of them to assist and help in order to get them better. In this sense, it is very important to bridge between human body and Cloud more intimately even though Cloud has got much attention to do anything for assisting and helping. So, in this Chapter, in addition of “Cloud at present”, Individual Cloud, Fog Computing, AI, VR, and AR have been added for the considerations.

However, the following things will be very important to study in the coming future:

1. To understand an individual thought of highly aged people towards life and living through Individual Cloud (and also Cloud, Fog Computing, AI, VR, AR, and MEMS).
2. To study much more about “MEMS” for the interface among human, electronics devices, and “Cloud in general”. This is the one of key issues for further advancements of this issue
3. To study about the transform mechanisms and behaviors of the highly aged people in order to moderate and to harmonize the transformations (Weakness ® Normal).
4. To study about VR (Virtual Reality), AR (Augmented Reality), and Cloud that should be used in harmonized and mixed methods in order to assist and to help the highly aged people.
5. To study about a communication method among the highly aged people by using verbal method, body language, gesture, eye contact, etc. in order to understand better.
6. To study about how to connect the related group of people in order to assist and help the highly aged people.

CONCLUSION

There have been more and more people who will live longer year by year. This phenomenon will become a global expansion of highly aged people. In this chapter, tried to find out what could be done by using the present high technologies in order not to cause troubles for those highly aged people. And studied about how to transform and how to strengthen the weakness to the normal for the highly aged people as shown below;

1. It was considered what sort of physical body and mental damages would come out to the highly aged people.
2. It was studied what sort of assistance and help would be needed for those damages.
3. It was studied what sort of assistance and help would be possible to use the present technologies; Cloud, Individual Cloud, Fog Computing, AI, VR, and AR.
4. It is understood that the present technologies are quite important for the highly aged people.

KEY TERMS AND DEFINITIONS

AI: Artificial intelligence.

AR: Augmented reality.

Cloud (Computing): Cloud computing is a way to offer a required and a necessary information for users that are retrieved through the internet.

Fog Computing: Decentralized computing infrastructure that data, storage, IoT, and software are distributed around in the most idealized and the most efficient place between the data source and cloud.

Highly Aged People: Group of people whose ages are over 75 years old (80 years old).

Individual Cloud: The cloud that is used only for an individual person through cloud from the internet.

MEMS: Micro-electronics mechanical systems.

MR: Mixed reality.

VR: Virtual reality.

Gene Editing Technology and Ethical Issues

Brooklyn Public Library, USA

INTRODUCTION

Technologies for making accurate additions, deletions, and alterations to DNA—have generated interest across the world because of the promise it holds to improve human health. For example, genome editing is being tested in clinical trials to engineer immune cells to target cancerous tumor cells and to make cells more resistant to HIV. Genome editing could also be used to develop new treatments for devastating genetic diseases like Huntington’s disease, sickle cell anemia, immune deficiencies, muscular dystrophy, and cystic fibrosis. Technology as tool view is only part of the story about the complex relationships between technology, society, and ethics. This is why technologies, are also complex social phenomena. Some technologies are encouraged by society through social demand or public funding. (Sandler R.L. 2014) This is often the case with medical technologies, while some technologies are opposed or rejected by society (or at least by some members of society)

Important inquiries have been raised about human genome editing and balancing potential benefits with the risk of unintended harms and using this type of technology while incorporating societal values into clinical applications and policy decisions. Furthermore, respecting the inevitable differences across nations and cultures that will shape diverse perspectives regarding these technologies. The recent development and growing use of the CRISPR/Cas9 system have resulted in an explosion of research in genome editing. Clinical trials are testing how these technologies can be used to improve health.

BACKGROUND

Five years ago University of California, Berkeley, biochemist Jennifer Doudna, and colleagues unveiled the gene-editing tool CRISPR (Science 2012). Doudna’s lab, in fact, was engaged in a patent fight with the Harvard- and MIT-affiliated Broad Institute.

The patent case turns on the question of which researchers at the two institutions conceived of the most important CRISPR applications first. UC says it’s a team at its Berkeley lab headed by Jennifer Doudna, with the collaboration of Emmanuelle Charpentier, now of Germany’s Helmholtz Centre for Infection Research. Broad’s claim is based on the work of its researcher Feng Zhang.

The patent office changed its rules to a “first-to-file” basis from the old “first-to-invent,” in 2013, making the U.S. the last major country to do so. The idea was to end disputes that turned on minute interpretations of lab records or personal notes, with costs that arguably disadvantaged small inventors.

Last February 2017, the U.S. Patent Trial and Appeal Board ruled that although a team led by UC Berkeley structural biologist Jennifer Doudna had first laid claim to the use of CRISPR to cut DNA in a

DOI: 10.4018/978-1-7998-3479-3.ch136

test tube, the use of the method on human cells by molecular biologist Feng Zhang's team at the Broad was still an advance.

However, a decision from the European Patent Office (EPO) in January 2018 revoked the patent from the Broad Institute of MIT and Harvard University because the Broad did not meet EPO requirements to establish that its researchers were the first to use CRISPR in eukaryotes. The patent granted to the Broad for fundamental aspects of the technology is one of several of its patents facing opposition in Europe.

Genome editing (also called gene editing) is a group of technologies that give scientists the ability to change an organism's DNA. These technologies can add, alter, or genetic material at particular locations in the genome. Several approaches to genome editing have been developed. Once the DNA is cut, researchers use the cell's own DNA repair machinery to add or delete pieces of genetic material, or altering the DNA by replacing an existing segment with a customized DNA sequence.

Genome editing is of great interest in the prevention and treatment of human diseases. It is being explored in research on a wide variety of diseases. It also holds promise for the treatment and prevention of a more complex disease, such as human immunodeficiency virus (HIV) infection.

Figure 1.

Clustered Regularly Interspaced Short Palindromic Repeats

One of most recent gene editing technology getting a lot of attention is CRISPR-Cas9. The CRISPR-Cas9 system has generated a lot of enthusiasm in the scientific community because it is faster, cheaper, more accurate, and more efficient than other existing genome editing methods.

CRISPR technology is a simple yet powerful tool for editing genomes. It allows researchers to easily alter DNA sequences and modify gene function. Its many potential applications include correcting genetic defects, treating and preventing the spread of diseases and improving crops. However, its promise also raises ethical concern (Vidyasagar A 2018).

CRISPR stands for Clustered Regularly Interspaced Short Palindromic Repeats, which is a sequence of base pairs found in the DNA of bacteria that have this feature. Some bacteria and archaea use CRISPR

for adaptive immunity, in order to incorporate bits of DNA from invading viruses into segments of their own DNA in order to target their immune system at those sequences.

CRISPR-Cas9 was adapted from a naturally occurring genome editing system in bacteria. The bacteria capture snippets of DNA from invading viruses and use them to create DNA segments known as CRISPR arrays. The CRISPR arrays allow the bacteria to “remember” the viruses (or closely related ones). If the viruses attack again, the bacteria produce RNA segments from the CRISPR arrays to target the viruses’ DNA. The bacteria then use Cas9 or a similar enzyme to cut the DNA apart, which disables the virus.

Figure 2.

CRISPR/Cas is an adaptive immune system (reviewed in Hryhorowicz et al. 2017) found in many bacteria and archaea, which enables effective defense against the invasion of bacteriophages or viruses. This immune system allows prokaryotes to “memorize” foreign DNA by incorporating its fragments into CRISPR arrays and ensures fast response to another infection in the future (Barrangou et al. 2007).

The CRISPR-Cas9 system works quasi like in the lab. Researchers create a small piece of RNA with a short “guide” sequence that attaches to a specific target sequence of DNA in a genome. The RNA also binds to the Cas9 enzyme. likewise, with bacteria, the modified RNA is used to recognize the DNA sequence, and the Cas9 enzyme cuts the DNA at the targeted location.

The CRISPR/Cas immune system performs its function in three general stages: adaptation, expression, and interference. During the first stage, short fragments of viral or phage DNA are incorporated into the CRISPR alignment. The integration of the new viral/phage DNA sequences is followed by duplication of a repeat, which in this way is forming a new spacer-repeat unit (Zych A O 2017). Spacer precursors called proto-spacers are selected from invading DNA depending on the recognition of neighboring protospacer-adjacent motifs (PAM). PAM sequences are typically several nucleotides long and vary among different variants of the CRISPR/Cas system (Makarova et al. 2011). The arrangement of spacers within the CRISPR alignment corresponds to the sequence of invasion events. In the next stage, CRISPR alignment is transcribed and primary transcript pre-crRNA is produced, which then is processed to mature CRISPR RNA (crRNA) by RNase III. Depending on the CRISPR/Cas system class, this process can be mediated either by multiprotein CRISPR ribonucleoprotein complex or a single protein (Zych, A.O).

Despite the variety of the CRISPR/Cas systems in nature, the most commonly used type adapted to genome editing is class 2 type II CRISPR/Cas9. CRISPR/Cas9 requires two short RNA sequences: crRNA and trans activating crRNA (tracrRNA) to recognize and cleave foreign DNA sequences. During the action of Cas9, the crRNA hybridizes with the tracrRNA forming duplex crRNA:tracrRNA, which in the next step associates with Cas9 (Zych, A.O). Despite the high efficiency, feasibility, and simplicity of target design CRISPR/Cas9 technique faces important complications. The essential limitation of this method is mutations at sites with similar but not identical homology to the target sites (Cradick et al. 2013).

There are several clinical trials in China investigating the efficacy of CRISPR/Cas9-mediated PD-1 knock-out T cells in patients with malignancies such as advanced esophageal carcinoma, muscle-invasive bladder cancer, metastatic renal cell carcinoma and others.

Gene-Editing Technology & Tools

Genome-editing tools all work in a similar fashion. They “target” specific DNA sequences for individual genes or non-coding regions by engineering certain proteins or protein-RNA complexes that can then recognize and bind the sequences and generate single-strand or double-strand DNA breaks. For example, a Cas9 protein along with a CRISPR “guide RNA” can find a target gene among the thousands of genes in a cell’s genome and cleave both DNA strands at the target site. Genome editing is already accelerating the pace of many areas of biology as researchers use genome-editing methods to more quickly and cheaply study the function of genes in model organisms and economically important species such as crops, livestock, and energy feedstock.

Figure 3.

Emerging Technologies and Ethical Concerns

Ethical technology tends to focus on the evaluation of emerging technologies and what might be problematic. The presumption is that new technologies are favorable. The question is not “why should we pursue or permit this new technology, but rather” are there any good reasons not to develop it”.

A prominent issue in the ethics of emerging technology is what role people's moral or religious concerns ought to play in developing policy and regulation.

When the potential of the CRISPR-Cas9 system was initially realized, ethical concerns were raised about the possibility of creating permanent and inheritable changes in the genome of human gametes and embryos. As a response to this development, a call for a moratorium was made for research involving genome modification of the human germline, or more specifically for the clinical applications of such technologies.

Most of the ethical discussions related to genome editing center around human germline editing. This is because changes made in the germline would be passed down to future generations.

Figure 4.

Bioethicists and researchers believe that human genome editing for reproductive purposes should be halted at this time, but continue studies that would make gene therapy safe and effective.

The first known attempt at creating genetically modified human embryos in the United States has been carried out by a team of researchers led by Shoukhrat Mitalipov of Oregon Health & Science University in Portland, Oregon in 2017. The effort, led by Shoukhrat Mitalipov of Oregon Health and Science University, involved changing the DNA of a large number of one-cell embryos with the gene-editing technique CRISPR, according to people familiar with the scientific results. Embryos were allowed to develop for more than a few days—and the researchers said there was never any intention of implanting them into a womb—the experiments are considered by many a milestone on what may prove to be an inevitable journey toward the birth of the first genetically modified humans.

Mitalipov and his collaborators showed they could bump up the efficiency of human embryo editing by inserting the CRISPR machinery earlier in development than previous experiments (Nature 548). When they combined healthy eggs with sperm bearing a disease-causing mutation and immediately added CRISPR, they found that 72% of the resulting embryos were free of the mutation—rather than the expected 50% that would have avoided inheriting the harmful gene anyway.

Although the researchers inserted short strands of DNA as templates for repair, the cells didn't seem to pick them up; those specific sequences were absent from the embryos. The team concluded that the cells must have relied instead on the non-mutated sequence in the egg donor's DNA when making the repairs.

Developmental biologist Maria Jasin of Memorial Sloan Kettering Cancer Center in New York City and Columbia University stem cell biologist Dieter Egli challenged that interpretation. The authors, including well-known CRISPR researcher and Harvard University geneticist George Church, say that the Nature paper goes against conventional wisdom about how embryos are organized early in development. Right after an egg is fertilized, the DNA from the sperm and the egg aren't believed to be in close enough proximity to interact or share genes, they explain.

Raising Ethical Questions

Bioethicists and researchers generally believe that human genome editing for reproductive purposes should not be attempted at this time, but that studies that would make gene therapy safe and effective should continue. Most agree that it is imperative to have continuing public deliberation and debate to allow the public to decide whether or not germline editing should be permissible.

The Hugo Committee

The Human Genome Organization (HUGO) has a long tradition of advocacy for 'benefit sharing' to realize societal as well as economic opportunities.

The HUGO Committee on Ethics, Law, and Society recently stated that 'genomic solidarity' ideally supports collaborations between individuals, communities, and populations, with research communities and industry. Significantly, benefit sharing and genomic solidarity work together through an idea of the public good. The public good is valued distributively, i.e., to each and every person that value is secured through equality of rights.

The idea of genomic solidarity is likely to be challenged, for it confronts the ingrained idea of public goods as something which hinders the benefits of economies of exclusion and rivalry. In that classical estimation, goods are 'public' depending on whether a private investment has any interest in them; in other words, if a good is profitable, then it is economically wasteful to consider it a public one. Paul Samuelson originally called it collective consumption goods (what later became known as 'public goods'). It leads to a particular view of goods that can be applied to the human genome.

Ethical Concerns and Gene Editing

Ethicists become concerned when germ cells are the target of CRISPR. Any changes in the germ cells can be potentially passed down for future generations, essentially introducing those changes into the human population.

Critics, however, worry that if the technology is developed to treat diseases it is a slippery slope to treating unwanted characteristics that are not actually diseases. Parents wanting stronger, smarter, taller children, for example, might be tempted by such technology.

Human intervention has long been discussed and debated in religious and spiritual terms. Christian traditions in the contemporary West, have had the most influence, on what today considered a most religiously diverse and secular culture. These ideas are expressed in the debate about which tasks in improving or stewarding nature are the domain and obligations of humans and which are left up to God.

With the Jewish tradition, there is an explicit obligation to build and develop the world that will be beneficial to human beings. Such improvements are viewed as a positive collaboration between God and humans and not as an interference with creation. (Steinberg, 2006). Muslim scholars and Jurists often respond to new technologies once they have already been introduced into Muslim societies. Assessment of such technologies is often taken in a piecemeal fashion. Technologies are analyzed on a case by case basis.

CRISPR-Cas9 forces scientists, ethicists and people of faith alike to consider where to draw the line on gene editing. There is a deep concern that couples will someday seek to create designer babies through gene editing.

Figure 5.

Furthermore, there is concern that genome editing will only be accessible to the wealthy and will increase existing disparities with access to health care and other interventions. Some worry that taken to its extreme, germline editing could create classes of individuals defined by the quality of their engineered genome.

Many people have moral and religious objections to the use of human embryos for research. Federal funds cannot be used for any research that creates or destroys embryos. In addition, NIH does not fund any use of gene editing in human embryos.

While new scientific advances have made gene editing easier and open possibilities for improved treatment and prevention of genetic diseases, the technology has risks, including the unintentional alteration of other genes, and ethical concerns, such as the introduction of mutations that will impact all future progeny.

Drawbacks and Challenges

Germline editing poses many important issues, including:

- the risks of inaccurate editing (such as off-target mutations) and incomplete editing of the cells of early-stage embryos (mosaicism);
- the difficulty of predicting harmful effects that genetic changes may have under the wide range of circumstances experienced by the human population, including interactions with other genetic variants and with the environment;
- the fact that, once introduced into the human population, genetic alterations would be difficult to remove and would not remain within any single community or country;
- the possibility that permanent genetic ‘enhancements’ to subsets of the population could exacerbate social inequities or be used coercively
- the moral and ethical considerations in purposefully altering human evolution using this technology.

Solutions & Recommendations

Possible Strategies for Working On The Immune System

- Instead of delivering CRISPR/Cas9 into the body, you take cells out of the body, use CRISPR to edit their genes in a lab, and return Cas9-free cells. This is the strategy pursued by CRISPR Therapeutics for the inherited blood disorder thalassemia and in various trials using CRISPR to modify immune cells to attack cancer
- Only use CRISPR in places the immune system cannot reach such as the eye. The immune system can’t really attack invaders there.
- It may be possible to redesign Cas9 to hide it from the immune system or to find other bacterial proteins that can do the job of Cas9 without provoking the immune response. Many different bacteria have CRISPR systems
- Researchers should use existing regulatory processes for human gene therapy to oversee somatic human genome editing research and uses
- Limit clinical trials or therapies to treatment and prevention of disease or disability at this time
- Evaluate safety and efficacy in the context of risks and benefits of intended use
- Researchers should permit clinical research trials only for compelling purposes of treating or preventing serious disease or disabilities, and only if there is a stringent oversight system able to limit uses to specified criteria
- Ongoing reassessment and public participation should precede any heritable germline editing Enhancement
- Scientists should not proceed at this time with human genome editing for purposes other than treatment or prevention of disease and disability
- Scientists should encourage public discussion and policy debate with respect to somatic human genome editing for uses other than treatment or prevention of disease and disability

FUTURE RESEARCH DIRECTIONS

Recently a nonpeer review study posted on bioRxiv 2018 reported that many people have existing immune proteins and cells primed to target the Cas9 proteins included in CRISPR complexes. That means those patients might be immune to CRISPR-based therapies or vulnerable to dangerous side effects — the latter being especially concerning as CRISPR treatments move closer to clinical trials. (Carsten C

et; al). Instead of successfully modifying the genome, when used therapeutically, the tool could trigger an adaptive immune response. The human body could treat Cas9 proteins as foreign bodies. This may trigger immune responses that would block gene therapy and pose a greater threat to the patient's health than the original disease they're treating for.

However, researchers not involved with the study said its findings, if substantiated, could be bypassed. Many of the first planned CRISPR clinical trials, for example, involve removing cells from patients, fixing their DNA, and then returning them to patients. In that case, it's possible that there will be few or no CRISPR proteins remaining for the immune system to detect. Researchers found that 79% of study participants produced antibodies against Cas9 derived from *S. aureus* and 65% from *S. pyogenes*.

As a safety precaution added to the CRISPR therapy protocol, at-risk patients could be screened before undergoing gene-editing treatment. A way around the immune system obstacle would be to develop other Cas9 enzymes from other bacteria that don't trigger an immune response.

CRISPR Therapeutics

CRISPR Therapeutics, based in Cambridge, Massachusetts, became the first company to ask permission from European regulators to begin a trial in 2018. The company will use the gene-editing technology on patients with beta thalassemia, an inherited blood disorder.

Daniel Anderson of the Massachusetts Institute of Technology, who has studied the delivery of CRISPR therapies, would like to conduct experiments to learn more. Likewise, Dr. Matthew Porteus and colleagues of Stanford, University is at work on a CRISPR-based therapy for sickle cell disease.

CRISPR Therapeutics is also planning to request approval from the U.S. Food and Drug Administration in the first half of 2018 to begin a CRISPR trial for sickle-cell disease. A Researcher Team led by Matthew Porteus, an associate professor of pediatrics at Stanford University School of Medicine are moving a CRISPR treatment for sickle-cell to clinical trials and plans to seek authorization from the FDA in 2018 to begin trials the following year

The center of the issue is a protein called Cas9, which is used as part of CRISPR-Cas9 to target and cut out specific sections of DNA. Without Cas9, CRISPR wouldn't work, but it's this specific protein that our bodies have learned to fight. Cas9 is typically found in harmful bacteria like *Staphylococcus aureus* and *Streptococcus pyogenes*, which cause staph and strep infections, respectively, so it's usually a good thing that our bodies fight the protein.

However, this does present a hurdle for researchers learning how to use CRISPR in human trials. There are already some tricks that researchers are using to circumvent the immune systems, like only using CRISPR outside of the body or in places that immune cells can't reach, but ultimately having to abandon Cas9 for a different protein that doesn't set off the bodies' defenses. CRISPR researchers could be facing a serious setback if this holds true.

CRISPR and AIDS

To eliminate the integrated HIV-1 genome, (Kaminski, R. *et al* 2016) used the Cas9/guide RNA (gRNA) system, in single and multiple configurations. The key components of CRISPR/Cas9 are guided RNAs (gRNAs) which determine specific sequence targeting of DNAs. Highly specific targets within the HIV-1 LTR U3 region were identified and efficiently edited by Cas9/gRNA, inactivating viral gene expression and replication in latently infected microglial, promonocytic, and T cells. Cas9/gRNAs caused neither genotoxicity nor off-target editing to the host cells, and completely excised a 9,709-bp fragment of

integrated proviral DNA that spanned from its 5' to 3' LTR. Furthermore, the presence of multiplex gRNAs within Cas9-expressing cells prevented HIV-1 infection. Their results suggest that Cas9/gRNA can be engineered to provide a specific, efficacious prophylactic and therapeutic approach to AIDS.

Figure 6.

The ultimate cure for HIV/AIDS will be the removal or disruption of integrated HIV provirus in latently infected cells or the elimination of these latent cells completely. (Zaohua H & Nair 2017)

FUTURE RESEARCH TRENDS

CRISPR Therapeutics AG & PESTEL Analysis

CRISPR Therapeutics AG PESTEL Analysis is a strategic tool to analyze the macro environment of the organization.

PESTEL stands for - Political, Economic, Social, Technological, Environmental & Legal factors that impact the macro environment of CRISPR Therapeutics AG.

Changes in the macro-environment factors can have a direct impact on not only the CRISPR Therapeutics AG but also can impact other players in the Biotechnology.

For example, an Industry may be highly profitable with a strong growth trajectory but it won't be any good for CRISPR Therapeutics AG if it is situated in the unstable political environment.

Two major concerns

Gene-edited products are subjected to the GMO's strict directive

1. Increased checks and controls would make it even more expensive for European academics and small companies to develop products for the market.
2. . the public could reject these products if they are considered GMOs, as was the case for genetically modified foods. CRISPR gene editing technology could play a key role in the fight against new

Table 1. CRISPR Therapeutics AG PESTEL & Environment Analysis

Political Factors that Impact CRISPR Therapeutics AG	● Political stability and importance of Biotechnology sector in the country's economy. ● Risk of military invasion ● Level of corruption - especially levels of regulation in Healthcare sector. ● Bureaucracy and interference in Biotechnology industry by government. ● Legal framework for contract enforcement ● Intellectual property protection ● Trade regulations & tariffs related to Healthcare ● Favored trading partners ● Anti-trust laws related to Biotechnology
Economic Factors that Impact CRISPR Therapeutics AG	Economic factors that CRISPR Therapeutics AG should consider while conducting PESTEL analysis are - ● Type of economic system in countries of operation – what type of economic system there is and how stable it is. ● Government intervention in the free market and related Healthcare ● Exchange rates & stability of host country currency. ● Efficiency of financial markets – Does CRISPR Therapeutics AG needs to raise capital in local market? ● Infrastructure quality in Biotechnology industry ● Comparative advantages of host country and Healthcare sector in the particular country. ● Skill level of workforce in Biotechnology industry. ● Education level in the economy
Social Factors that Impact CRISPR Therapeutics AG	Social factors that leadership of CRISPR Therapeutics AG should analyze for PESTEL analysis are - ● Demographics and skill level of the population ● Class structure, hierarchy and power structure in the society. ● Education level as well as education standard in the CRISPR Therapeutics AG 's industry ● Culture (gender roles, social conventions etc.) ● Entrepreneurial spirit and broader nature of the society. Some societies encourage entrepreneurship while some don't. ● Attitudes (health, environmental consciousness, etc.) ● Leisure interests
Technological Factors that Impact CRISPR Therapeutics AG	A firm should not only do technological analysis of the industry but also the speed at which technology disrupts that industry. Slow speed will give more time while fast speed of technological disruption may give a firm little time to cope and be profitable. Technology analysis involves understanding the following impacts - ● Recent technological developments by CRISPR Therapeutics AG competitors ● Technology's impact on product offering ● Impact on cost structure in Biotechnology industry ● Impact on value chain structure in Healthcare sector ● Rate of technological diffusion
Environmental Factors that Impact CRISPR Therapeutics AG	Before entering new markets or starting a new business in existing market the firm should carefully evaluate the environmental standards that are required to operate in those markets. Some of the environmental factors that a firm should consider beforehand are - ● Weather ● Climate change ● Laws regulating environment pollution ● Air and water pollution regulations in Biotechnology industry ● Recycling ● Waste management in Healthcare sector ● Attitudes toward "green" or ecological products ● Endangered species ● Attitudes toward and support for renewable energy
Legal Factors that Impact CRISPR Therapeutics AG	● Anti-trust law in Biotechnology industry and overall in the country. ● Discrimination law ● Copyright, patents / Intellectual property law ● Consumer protection and e-commerce ● Employment law ● Health and safety law ● Data Protection

diseases that arrive in Europe due to globalization and climate change, so the prospect of slowing their progress even further is worrying.

What's more, it appears that there is nothing stopping individual EU member states from making their own rules for gene editing. This raises the possibility that there could be a patchwork of different rules across the continent, which could undermine the single market

CONCLUSION

The development of CRISPR–Cas9 as an effective genome-editing tool is under perusal because it brings with it the possibility that scientists could make permanent modifications to the human germline.

Scientists and medical personnel have been publishing their research experiments since the onset of CRISPR. The single, major giant that supports biomedical sciences, including genomics, is 'the public' or, realistically, a constellation of all public. The concept of the public good has been articulated as solidarity, a community that finds it worthy to protect the shared interests of research. Regulators, funders, scientists, and editors need to continue working together to define the details of the path forward for germline genome editing so that the valuable resources and tools now at our disposal are used with good judgment.

The Beijing-based researchers have already used Crispr to take a version of UPC1 from mice and inserted it into pig embryos, which they then implanted into 13 female pigs. Three of them became pregnant and gave birth to 12 piglets, and subsequently, low-fat bacon was created.

Figure 7.

Public education and engagement are crucial in the process of assessing and applying societal values to the risks and benefits of genome editing technologies and the ethical dimensions they involve. There should be active participation and input by the public, along with an ongoing reassessment of both health and societal benefits and risks, before moving clinical trials ahead.

While researchers keep refining the gene editing tool, CRISPR is becoming very popular among DIY scientists and biohackers. Some believe that the relatively simple methods that this technique requires

might help democratize science and bring it closer to people outside the lab. However, some recent cases of biohackers injecting themselves with experimental treatments have alarmed the public and it remains to be seen how these uses will be regulated

KEY TERMS AND DEFINITIONS

CRISPR/Cas9-CRISPR-Cas Systems: Prokaryotic immune systems that confer resistance to foreign genetic elements such as plasmids and phages. CRISPR-Cas systems have been exploited for targeted genome editing.

Ethical Technology: Tends to focus on the evaluation of emerging technologies and what might be problematic.

Genome Editing: Genome editing or genome editing with engineered nucleases (GEEN) is a type of genetic engineering in which DNA is inserted, deleted or replaced in the genome of a living organism using engineered nucleases, or “molecular scissors.”

Germline Editing: Human germline engineering is the process by which the genome of an individual is edited in such a way that the change is heritable.

Human Germline Engineering: The process by which the genome of an individual is edited in such a way that the change is heritable.

Mosaicism: A condition in which cells within the same person have a different genetic makeup.

About the Contributors

Mehdi Khosrow-Pour, D.B.A., received his Doctorate in Business Administration from the Nova Southeastern University (Florida, USA). Dr. Khosrow-Pour taught undergraduate and graduate information system courses at the Pennsylvania State University – Harrisburg for almost 20 years. He is currently Executive Editor at IGI Global (www.igi-global.com). He also serves as Executive Director of the Information Resources Management Association (IRMA) (www.irma-international.org) and Executive Director of the World Forgotten Children Foundation (www.worldforgottenchildren.org). He is the author/editor of more than 100 books in information technology management. He is also currently the Editor-in-Chief of the *International Journal of E-Politics (IJEP)* and the *International Journal of Semiotics and Visual Rhetoric (IJSVR)*, and is also the founding Editor-in-Chief of the *Information Resources Management Journal (IRMJ)*, *Journal of Electronic Commerce in Organizations (JECO)*, *Journal of Cases on Information Technology (JCIT)*, and the *Journal of Information Technology Research (JITR)*, and has authored more than 50 articles published in various conference proceedings and scholarly journals.

Balikis Animasaun Abdul-Jeleel holds an OND from the Polytechnic of Ibadan, a B.Sc in Computer Science from the University of Ibadan and MSc in Information Science from the Africa Regional Centre for Information Science, University of Ibadan. She is presently a service desk and procurement analyst at the International Institute of Tropical Agriculture (IITA), Ibadan, Nigeria.

C. Abinaya is a student at Thiagarajar College of Engineering. Her research area include Network and Information Security.

Hisham Abusaada is a Professor of Architecture and Urban Design at the Housing and Building National Research Centre (HBRC), Egypt. During 1995-2015, he taught urban design course at universities in Saudi Arabia and Egypt. He is the author and co-authors of several scientific manuscripts and books in both Arabic and English published in scientific journals and conference proceedings. His area of interest is in urban design between theory and practice.

Olga Acosta is a PhD in Computer Sciences at the UNAM (México) in 2013. CTO of Singularityta SpA (2019).

About the Contributors

César Aguilar is a PhD in Linguistics at the UNAM (Mexico) in 2009. Assistant Professor at the Pontificia Universidad Católica de Chile.

Rukhsana Ahmed (PhD, Ohio University) is Associate Professor and Chair in the Department of Communication and Research Associate at the Center for the Elimination of Minority Health Disparities, University at Albany, State University of New York, USA. Her primary research interests lie at the intersections of health, organizational, interpersonal, and intercultural communication. In particular, her research embraces the cross/trans/inter-disciplinary nature of communication scholarship, with specific focus on exploring the role of communication processes in improving health outcomes among marginalized communities and promoting broader organizational and social changes and innovations in local, national, and international health contexts. Her collaborative and partnership research projects have been funded by Federal Government Agencies and Not-For-Profit Organization, and she has presented and published top papers and an award winning book at the intersection of health communication, service quality, culture, and media in respected international interdisciplinary and transdisciplinary conferences and peer-reviewed publication outlets. She is the Chief Editor of Health Communication, specialty section of *Frontiers in Communication*.

Kolawole Sunday Akinsunmbo is an information technology consultant, programming instructor, management training facilitator, startup management consultant and professional B2B deal broker. I have worked with brands across Nigeria as an I.T and Management consultant to deliver ease of business process, employee retention and develop effective and efficient organisational modus operandi. Kolawole is a Certified Web Programmer and Building Android and iOS Apps with Dreamweaver CC and PhoneGap (certified by Lynda.com). He a graduate member of the Nigeria Institute of Management, Certified Entrepreneurial Professional by Osun State University where I also obtained a Bachelor of Science (B.Sc) Hons in Business Administration.

Rashida Mebude Aligiwa is an O365 Support Engineer at Tek Experts. She holds a B.Sc in Physics from the Ahmadu Bello University, Zaria and a Master of Information Science (M.Inf.Sc) degree of the Africa Regional Centre for Information Science (ARCIS), University of Ibadan, Nigeria.

Fernando Luís Almeida has a PhD in Computer Science Engineering from Faculty of Engineering of University of Porto (FEUP). He holds also MSc in Innovation and Entrepreneurship and MSc in Informatics Engineering from FEUP. He has around 7 years of teaching experience at higher education levels in the field of computer science and management. He has also worked for 10 years in several positions as software engineer and project manager for large organizations and research centers like Critical Software, CICA/SEF, INESC TEC and ISR Porto. During that time he had the possibility to work in partnership with big international organizations and universities in several European projects. His current research areas include innovation policies, entrepreneurship, software development and decision support systems.

Mohammad Nabil Almunawar is currently a senior assistant professor at School of Business and Economics, Universiti of Brunei Darussalam (UBDSBE), Brunei Darussalam. He was the former dean of UBDSBE. He received his bachelor degree in 1983 from Bogor Agricultural University, Indonesia, master Degree (MSc Computer Science) from the Department of Computer Science, University of Western Ontario, London, Canada in 1991 and Ph.D. from the University of New South Wales (School of

Computer Science and Engineering, UNSW) in 1998. Dr Almunawar has published more than 80 papers in refereed journals, book chapters and international conferences. He has more than 30 years teaching experiences in the area computer and information systems. His overall research interests include applications of IT in Management, Electronic Business/Commerce, Health Informatics, information security, cloud computing, Big Data and Internet of Things. He is also interested in object-oriented technology, databases and multimedia retrieval.

Justinah Amoko is Lecturer at Department of Chemistry, Adeyemi College of Education Ondo.

Maria Teresa Artese took her degree in Computer Science at the University of Studies of Milan in 1990. She has been working at the CNR since 2000. Now she works at IMATI – CNR Unit of Milan. Dr. Artese major areas of work are functional analysis and software development, technical support, database structuring and development, dynamic web database sites, design, and implementation. Recently she has focused his research on multimedia information systems development and data online management. On these topics, she has several national and international publications, and she has been working in national and international research projects.

Artem Artyukhov is a member of Processes and Equipment of Chemical and Petroleum-Refineries Department. Research areas: 1. Mathematical modeling of the main processes and devices of chemical technology. 2. Optimization calculations of equipment for chemical production. 3. Creation of three-dimensional models of technological units and equipment. 4. Computer simulation of hydromechanical and heat-mass transfer processes in chemical technology. 5. Development of new types of heat-mass transfer equipment with the use of swirling flows.

Nadiia Artyukhova is a member of Processes and Equipment of Chemical and Petroleum-Refineries Department. Research areas: 1. Mathematical modeling of the main processes and devices of chemical technology. 2. Optimization calculations of equipment for chemical production. 3. Computer simulation of hydromechanical and heat-mass transfer processes in chemical technology. 4. Development of technological and design documentation for the manufacturing of equipment for chemical production. 5. Development of new types of drying equipment.

Udo Richard Franz Averweg is employed as an Information Technology (IT) Project Manager at eThekwin Municipality, Durban, South Africa. He entered the IT industry during 1979 and holds a Masters Technology degree in Information Technology (cum laude), a second Masters degree in Science from the University of Natal and a third Masters degree in Commerce from the University of KwaZulu-Natal, Durban, South Africa. As an IT practitioner, he is a registered professional member of the Institute of Information Technology Professionals in South Africa. He has authored and co-authored more than 190 research outputs (90 being peer-reviewed): some research outputs have been delivered at local and international conferences, some have been published in accredited peer-reviewed journals and some have appeared as chapters in books. During January 2000 Udo climbed to the summit of Africa's highest peak, Mount Kilimanjaro (5,895 metres), in Tanzania.

Samuel Oyelami Babalola works in Sales and Marketing department of Livestock Feeds Plc (subsidiary of UAC Nigeria Plc), Lagos, Nigeria. He has previously functioned as a Research & extension Officer,

About the Contributors

and Data analyst in different organisations. He holds a Bachelor of Agriculture in Agricultural Extension and Rural Development from the University of Ibadan, Nigeria. He also holds a Master in Information Science degree (M.Inf.Sc) from the University of Ibadan, Nigeria. His research interest includes Business development and Market research, ICT and society, Business informatics and Knowledge Management.

Grace Babcock received her B.A. in Sociology from North Carolina State University in May of 2019. She will receive her J.D. from the University of South Carolina School of Law in May of 2022. Her research interests include maternal employment and gender disparities in the legal profession.

Abira Banik completed her B.E. degree in Computer Science & Engineering from Tripura Institute of Technology, Agartala in 2015. She has completed M.Tech. in Computer Science & Engineering from Department of Computer Science & Engineering, Tripura University (A Central University), Suryamaninagar, India in 2018. Her research interest includes Wireless Mesh Network, MANET and QoS provisioning.

Diane Barrett is an associate professor. She has done forensic, incident response, and security assessment work for many years holding titles such as Manager of research and training for cyber, mobile forensic training director, and enterprise engineer. She has served as a program director for ADFSL's Conference on Digital Forensics, Security, and Law and is a volunteer on the National CyberWatch Center's Curriculum Standards Panel as well as NIST's Cloud Computing Forensic Science Working Group. Dr. Barrett served for several years as the President of the Digital Forensics Certification Board. Dr. Barrett's education includes a Ph.D. in business administration with a specialization in information security. She holds many industry security certifications and has authored multiple security and forensic books.

Amit Bhagat is working as an Assistant Professor at the National Institute of Science & Technology, Bhopal. His expert area is Big Data, Machine Learning, and IoT. More than 10 papers are published in international journals and presented many papers at international conferences. He guided many research scholars who are working in various areas of computer science.

Tulshi Bezboruah (M'12) received the B.Sc. degree in physics with electronics from the University of Dibrugarh, Dibrugarh, India, in 1990, and the M.Sc. and Ph.D. degrees in electronics and radio physics from the University of Gauhati, Guwahati, India, in 1993 and 1999, respectively. In 2000, he joined in the Department of Electronics Science, Gauhati University, as a Lecturer. He is currently the Professor & Head, Department of Electronics and Communication Technology, Gauhati University. His current research interests include instrumentation and control, distributed computing, and computer networks. Prof. Bezboruah is a senior member of the IEEE, and Vice Chair of IEEE Geoscience and Remote Sensing Society (IEEE GRSS), Kolkata chapter as well as an Associate Member of the International Center for Theoretical Physics, Trieste, Italy.

Cristina Boido has a degree in Architecture, specialization in History, Analysis and Development of Architectural and Landscape Heritage at the Politecnico di Torino, research Doctorate in Drawing and Survey of Architectural Heritage at the Università "La Sapienza" di Roma, associate professor of Drawing at the Department of Architecture and Design of the Politecnico di Torino from December 2010. Currently she teaches a class of Representation in the Territorial, Urban, Environmental and Landscape Planning

Laurea and in the Atelier Compatibility and sustainability of architectural restoration in Master's degree programmes of the Architecture for Sustainable Design. Cristina Boido has in depth knowledge of the problems linked to Drawing and Representation, and in particular to architectural, urban and landscape surveying, using digital representation techniques.

Abhijit Bora received Master of Computer Applications (MCA) degree from Jorhat Engineering College (Under Dibrugarh University), India in 2008 and Ph.D from Gauhati University, India in the year 2017. His research interests include web service, web security and software engineering.

Roula Borhani obtained her Bachelor degree in electronic marketing and digital strategy with honors from Higher School of Digital Economy of Manouba (Tunisia) in 2019. She is preparing a master's degree in management of social and solidarity organizations at the High Institute of Management of Tunis. She practices in the areas of digital marketing and social media. She has more than 10 years of experience as a communication manager and content editor in international companies. She is a member of various non-governmental organizations working in the field of human resource development (OMEDRH, AFK).

Djelloul Bouchiha received his Engineer degree in computer science from Sidi Bel Abbes University, Algeria, in 2002, and M. Sc. in computer science from Sidi Bel Abbes University, Algeria, in 2005, and Ph. D. in 2011. Between 2005 and 2010, he joined the Department of Computer Science, Saida University, Algeria, as a Lecturer. He became an Associate Professor since September 2013. Currently, he is a Full Professor at the University Center of Naama. His research interests include software engineering, semantic Web services, Web reverse-engineering, ontology engineering, knowledge management and information systems.

Charalampos Bratsas teaches at the Mathematics Department of the Aristotle University of Thessaloniki. He is the founder of the Greek Chapter of the Open Knowledge Foundation and the President of its Administration Board. He is a specialist in Semantic Web with a focus on Linked Open Data Internationalization and Ontology engineering. His research interests include Data Mining algorithms, Semantic Web, Social Semantic Web, Internationalization of Linked Data, he is coordinator of Greek DBPedia, Applications of Statistical Knowledge, Data Journalism, as well as Neuroinformatics. His research has appeared in the Journal of Web Semantics: Science, Services and Agents on the World Wide Web, in IEEE Transactions on Information Technology in Biomedicine, in the Journal of Computer Methods and Programs in Biomedicine, in BMC Medical Education, and others.

Sheldondra Brown is a student at Southeast Missouri State University to receive her Bachelor of Science in Psychology. Some of her research interest include cultural identity, group dynamics, race relations, cognitive psychology, and mental health outreach.

Tomas Cahlik is Associate Professor of Economics at the Institute of Economic Studies, Charles University in Prague, Czech Republic. His research and teaching activities are currently in Comparative Economics and Ethics and Economics.

Pedro Campos is an assistant professor at the Faculty of Economics of the University of Porto (UP), with a PhD in Management Sciences by U. Porto, Bsc in Applied Mathematics (U. Portucalense). He is

About the Contributors

a member of LIAAD (Laboratory of Artificial Intelligence and Decision Support), which is a research group belonging to INESC TEC. He coordinates the Post-Graduate Programme on Business Intelligence and Analytics at the University of Porto Business School. Pedro is actually Deputy Director of the international Statistical Literacy Project (ISLP) and Vice President of IASE - International Association of Statistical Education His main research interests are Statistics (Data Analysis, Sampling Techniques, Statistical Education) and Artificial Intelligence (Multi-Agent Systems). The main areas of applications are Demography and Organizational Networks.

Manuel Caro is Head of Department of Educational Informatics Universidad de Córdoba Professor in Educational Informatics - Unicordoba Software Engineering Specialist - Udistrital Bogotá Master in ICT for education - IUP - Spain Ph.D. Engineering - Systems and Informatics - UNAL – Medellín.

A. R. Chabukswar completed his B. Pharm. (1998) from Pune University, M. Pharm. (2000) from Mumbai University and Ph. D. (2009) from Shivaji University Kolhapur. He is presently working as Professor & HOD Pharmaceutical Chemistry at School of Pharmacy, Dr. Vishwanath Karad MIT world Peace University, Pune from 19th September 2000. He is actively involved in Academic, research and administrative activities of Pharmacy school. He has published more than 60 research articles in referred Journals. He has co-authored 5 books. He has filed 2 Indian patents. He has completed 2 minor research projects of Savitribai Phule Pune University. He has received research grants from DST and CSIR. He has received Best Professor in Pharmaceutical Chemistry Award in 11th Innovative Education Leadership Award by DNA on 16th February 2019. Awarded as Ideal Teacher award by MAEER's Maharashtra Institute of Technology in 2008. He has guided 47 M.Pharm students and 02 Ph.D students. Presently 06 students of M.Pharm and 03 students of Ph.D. are working on their project under his guidance.

Pankaj Chaudhary is currently Professor of MIS in the ISDS department at Indiana University of Pennsylvania, USA. He holds a PhD in MIS from Southern Illinois University, USA, an MBA from Indian Institute of Management, Ahmedabad, India, and Bachelor of Technology in Computer Science & Engineering from Indian Institute of Technology, Delhi, India. His current research areas include Information Systems Agility, IS Infrastructure, IS-Centric organizational transformation, and Knowledge Management.

Nutan Kumari Chauhan is an Assistant Professor at KIET Group of Institution, Ghaziabad, India. She did her Ph.D. in 2019 from Gurukula Kangari Vishwavidyalaya Haridwar, 249404, Uttarakhand India. Her area of research is Distributed Fuzzy System. She has also qualified CSIR NET-JRF. She has published five research paper in International Journals.

E. Jack Chen is a Senior Staff Specialist with BASF Corporation. He received a Ph.D. degree from University of Cincinnati. His research interests are in the area of computer simulation.

Dilip Kumar Choubey received his Ph.D in Engineering from Birla Institute of Technology (B.I.T), Mesra, Ranchi, India in 2018. He received his M.Tech degree in Computer Science and Engineering from Oriental College of Technology (O.C.T), Bhopal, India in 2012 and has B.E. degree in Information Technology from Bansal Institute of Science and Technology (B.I.S.T), Bhopal, India in 2010. Currently, He is working as an Assistant Professor (On Contract) in NIT Patna, India since March 2017. He

worked as an Asst. Prof. in Lakshmi Narain College of Technology (L.N.C.T), Bhopal, India and Oriental College of Technology (O.C.T), Bhopal, India. He has more than 7 years of teaching and research experience. He is a author of 1 book and has more than 19 research publications in international journals, book chapters and conference proceedings to his credit. He has been the member of the organizing and technical program committees of some conferences and Workshop. He has reviewed several research papers in reputed journal. He has been attended so many workshop's/Seminar's/Conference's. He is the lifetime members of several professional bodies such as The International Association of Engineers (IAENG), The Internet Society Switzerland (ISOC), The Society of Digital Information and Wireless Communications (SDIWC), Universal Association of Computers and Electronics Engineers (UACEE), Associate Member (till 4 May, 2019), Computer Science Teachers Association (CSTA), etc. His research interests include Machine Learning, Soft Computing, Bioinformatics, Data Mining, Pattern Recognition, and Database Management System, etc.

Mahfuzulhoq Chowdhury received the BSc degree in computer science and engineering from Chittagong University of Engineering and Technology, Bangladesh, in 2010, and the MSc degree in computer science and engineering from Chittagong University of Engineering and Technology, in January 2015. He is currently working toward the PhD degree in INRS working on the Tactile Internet. His current research interests include collaborative computing, fiber-wireless multi-robot networks, human-to-robot communications, and Tactile Internet.

Nkiko Christopher is the current University Librarian of Elizade University. Prior to joining the services of Elizade University, he had a stint for a year at Samuel Adegboyega University in the same capacity after a successful tenure as the University Librarian of Covenant University. He holds B.Sc in Political Science from the University of Benin, Edo State, M.Sc in Political Science, MLS and Ph.D in Library and Information Studies from the University of Ibadan. He holds Chief Oduaran Memorial Prize (1988) for being the best graduating student in Political Science, Chief Anthony Enahoro's Prize for being the best overall student in Nigerian Government and Politics (1988) and NYSC, Kano State Merit Award for Exemplary Character and Distinguished Hardwork (1989), LARISSA, University of Ibadan (2012) Distinguished Personality Award for Selfless Service to Librarianship and Information Profession, Award for Effective Archival System and Valid Contribution to Scholarship in Covenant University (Covenant University 2014-2015 Awards and Recognition). Dr. Nkiko has had the privilege of international study visits to benchmark the following United Kingdom and American libraries: British Library (London), Lancaster University Library, Birmingham City University Library, Aston University Library, Birmingham, University of Sussex, Brighton, Fayetteville State University Library, North Carolina State University Library, North Carolina Central University Library and Calvin College Library, Grand Rapids, Michigan. He is an Associate member of the Chartered Institute of Library and Information Professionals (CILIP) UK, member of the Nigerian Library Association, member of the Association of University Librarians of Nigerian Universities and a Certified Librarian (CLN) of the Librarians' Registration Council of Nigeria. Dr. Nkiko has published extensively in local and international (SCOPUS and Web of Science-indexed) journals. He is on the editorial boards of many reputable journals.

Vera Costa has a degree in Mathematics at the Faculty of Sciences of the University of Porto and a Master Degree in Data Analysis and Decision Support Systems at the Faculty of Economics of the same university. She started to teach mathematics to high school and, after that, information systems to

About the Contributors

college students. She participated in several research projects, and she contributes with her knowledge of statistical analysis and software programming, in different application fields, such as health, politics, and transportation. Currently, she is a Ph.D. student of Transportation Systems of the MIT Portugal program.

Kevin Curran is a Professor of Cyber Security, Executive Co-Director of the Legal innovation Centre and group leader of the Ambient Intelligence & Virtual Worlds Research Group at Ulster University. His achievements include winning and managing UK & European Framework projects and Technology Transfer Schemes. Professor Curran has made significant contributions to advancing the knowledge and understanding of computer networks and security, evidenced by over 800 published works. His expertise has been acknowledged by invitations to present his work at international conferences, overseas universities and research laboratories. He is a regular contributor to print, online, radio & TV news on computing & security issues. He was the recipient of an Engineering and Technology Board Visiting Lectureship for Exceptional Engineers and is an IEEE Public Visibility technical expert since 2008. He currently holds a Royal Academy of Engineering/Leverhulme Trust Senior Research Fellowship awarded in 2016. Professor Curran's stature and authority in the international community is demonstrated by his influence, particularly in relation to the direction of research in computer science. He has chaired sessions and participated in the organising committees for many highly-respected international conferences and workshops. He was the founding Editor in Chief of the International Journal of Ambient Computing and Intelligence and is also a member of numerous Journal Editorial boards and international conference organising committees. He has authored a number of books and is the recipient of various patents. He has served as an advisor to the British Computer Society in regard to the computer industry standards and is a member of BCS and IEEE Technology Specialist Groups and various other professional bodies.

Arpita Das received her B. Tech, M.tech degrees in Radio Physics and Electronics University of Calcutta, India in the year 2004 and 2006 respectively. She received her Ph.D. degree in 2012 from University of Calcutta. Currently she is an Assistant Professor in the Dept. of Radio Physics and Electronics.

Kaustav Das is an M.Tech student in the Dept. of Radio Physics and Electronics, University of Calcutta, India. He received his B.Tech degree in Radio Physics and Electronics in the year 2018.

Aristides Dasso is currently a Visiting Professor at the Departamento de Informática at Universidad Nacional de San Luis, Argentina. He has degrees from Universidad Nacional del Litoral, Rosario, Argentina (Political Science); Université de Paris VII, Paris, France (Computer Science) and Universidad Nacional de San Luis (Master in Software Engineering). He has been a fellow at the International Institute for Software Technologies of the United Nations University, Macau; and was at Universitat Politècnica de València, Spain, with a scholarship from the European Community ALFA LERnet program. He is a member of ACM, IEEE, and SADIO of Argentina. He have published more than fifty articles in international conferences and journals on Software Engineering and Information Systems, areas of research that he is currently pursuing, with special emphasis in the area of Formal Methods and Machine Learning. He have served and is serving as referee in several conferences both national and international.

Pia Davico is Architect, Adjunct Professor of Drawing and Representation, and Assistant Professor at the Politecnico di Torino, Department of Architecture and Design (DAD); Ph.D. in "Drawing and survey of Architectural Heritage" at the Università "La Sapienza" di Roma. Teacher in the "School of

Specialization on Architecture and Landscape Heritage” of Politecnico di Torino, in Ateliers of the master degree course “Architecture for the sustainable projects” and in the “Laboratory of Drawing and Survey”. Reviewer for some important international magazines. She participated in scientific research groups, in consulting projects for public Institutions, in National and International Conferences with numerous oral relations and written researches. She always privileged the interest for architecture survey inserted in its own context, which provided a variety of original experiences through collaborations with the Public Administrations. The survey considered the study of the historical transformations of the built and the on-site analysis of urban structure to different scales: from relationship with the local territory to buildings. In this way the environmental and architectural characters were identified, including the color, with perceptive and functional studies.

José C. Delgado is an Associate Professor at the Computer Science and Engineering Department of the Instituto Superior Técnico (University of Lisbon), in Lisbon, Portugal, where he earned the Ph.D. degree in 1988. He lectures courses in the areas of Computer Architecture, Information Technology and Service Engineering. He has performed several management roles in his faculty, namely Director of the Taguspark campus, near Lisbon, and Coordinator of the B.Sc. and M.Sc. in Computer Science and Engineering at that campus. He has been the coordinator of and researcher in several international research projects. As an author, his publications include one book, 25 book chapters and more than 50 papers in international refereed conferences and journals.

Suparna Dhar is a senior manager in an IT organization with focus on developing IT solutions for the Fintech space and exploring emerging technologies. She takes interest in academic research on application, adoption and use of emerging technologies in business, covering analytics, social media technologies, cloud computing, distributed processing and blockchain. She is pursuing her PHD on Information Systems Management from Aligarh Muslim University.

Ljubica Diković is an Assistant Professor at the Faculty of Applied Economics, Management and Finance at the University of Business Academy Novi Sad, and a Professor of vocational studies at the College of Applied Studies Uzice. She was awarded MSc degree by the Faculty of Science, University of Belgrade. She enrolled in PhD studies at the Faculty of Science, University of Kragujevac and acquired the title of PhD in Mathematical Sciences. She has participated in a number of projects funded by the European Union. She has been the author of several articles published in international and national journals, and of more than 40 papers written for international and national conferences.

Gregor Donaj made his B.Sc. degrees in Electrical Engineering and Mathematics in 2010 and 2011 respectively. He obtained his Ph.D. in 2015. From 2010 to 2014 he was a researcher, and from 2014 onward he is a teaching assistant at the Faculty of Electrical Engineering and Computer Science of the University of Maribor. His primary research areas are language modeling and error analysis in speech recognition and machine translation.

Jorge Doorn is Full Professor of Universidad Nacional del Oeste and Universidad Nacional de Tres de Febrero, Argentina. His current research interest is on Requirements Engineering field.

About the Contributors

Dinah Duarte is Professor at Universidade Lusófona's Research Center for Biosciences and Health Technologies, Portugal.

Robert Andrew Dunn is assistant chair for the Department of Media and Communication at East Tennessee State University. He is also an associate professor and head of the journalism program. He teaches both journalism and mass communication courses. Academically, Dunn holds a Ph.D. in mass communication from the University of Alabama, a master's degree in mass communication from Florida State University, and a bachelor's degree in mass communication from Auburn University Montgomery. Professionally, Dunn worked in newspapers for nearly a decade. He served primarily as an education reporter and occasional legislative reporter for both the Tallahassee Democrat in Tallahassee, Florida, and The Ledger in Lakeland, Florida. He has also served as an instructor for Florida Southern College and the University of Alabama. Dunn's research focuses on avatars, virtual identity, mediated identity, media psychology, media effects, fandom, and communication technology. He also has a strong interest in journalism and media convergence. He is an avid gamer, dedicated sports fanatic, expert comic collector, enthusiastic sci-fi/fantasy devotee, frequent fan convention attendee, and Belgian beer buff.

Justina Ngozi Ekere a Chartered Librarian, is presently a Principal Librarian and Head of Reference Section, Nnamdi Azikiwe Library University of Nigeria Nsukka. She is a holder of B.Sc. (Hons); M.L.S and a Ph.D in Library and Information Science. She is a multifaceted library practitioner, educator and also a seasoned administrator. In 1997, she was employed as an Assistant Librarian and today she has over Twenty-Three (23) years post qualification and cognate experience. Dr. Ekere is creative and thorough. She has initiative and a cheerful disposition which enable her to get on with her superiors and peers. In 2004, the Governing Board of the American Biographical Institute (ABI) in recognition of her significant accomplishments within, and mastery of library and Information Science, conferred on her GREAT WOMAN OF THE 21ST CENTURY, a title reserved for women whose accomplishments and influence are the result of superior dedication and professional integrity. She is a member of professional associations such as Nigerian Library Association (NLA) AFLIA, IFLA, African Centre of Excellence for Information Ethics (ANIE) and WALA). Her Research and Scholarly Interest includes; Indigenous Knowledge Management, Human Resource Management, Information Ethics and ICT applications to library operations.

Abeer Elshater PhD, is a Professor of Urban Morphology at Ain Shams University (ASU), Cairo, Egypt, teaching and supervising multidisciplinary topics in the ideology of urban design. Her area of interest is in urban design disciplines. She has worked on some international research projects with international universities. Elshater is an author and co-author of seven books as well as a number of scientific manuscripts in international journals and conference proceedings. Recently, she acts as an ambassador of the Regional Studies Association, United Kingdom.

Arzu Erener graduated from the Department of Geodesy and Photogrammetry Engineering at Istanbul Technical University (ITU) in 1999, she has completed a master's education while working as a research assistant in the Geodesy and Photogrammetry Department at Karadeniz Technical University (KTU) between 2000-2002. Researcher completed her doctorate from the Middle East Technical University (METU), in 2010, while serving as a research assistant between 2002-2009. She worked as research assistant doctor in Selcuk University (SU) Geomatics Engineering Department and got her professorship

at 18 January 2013. Currently she is working as Assoc. Prof. Dr. at Geomatics Engineering Department of Kocaeli University and gives courses on Remote Sensing, GIS and Risk Management. Since 2015, she has been working as the head of Geomatic Engineering Department.

Monday Ofori Eyinagho holds a B.Sc. Degree in Electronic and Electrical Engineering, an M.Sc. Degree in Computer Engineering, an MBA Degree in General Management, and a Ph. D in Computer Engineering. He is currently a Senior Lecturer in the Department of Electrical and Computer Engineering, Afe Babalola University, Ado-Ekiti, Nigeria. His principal researches are in the areas of development and implementation of microprocessor-based systems, performance optimization of Local Area Computer Networks, Wireless Sensor Networks, Internet of Things, Digital and Microprocessor-based Instrumentation Systems. He is a Life Member of the Nigeria Computer Society, Member of the Nigerian Society of Engineers, a Council for the Regulation of Engineering in Nigeria Registered Electronic Engineer.

Michael O. Fagbohun is a seasoned professional librarian with an unusual passion for youth mentoring. He is a multi-talented individual that seamlessly combines professionalism with research and social entrepreneurship. He holds a Bachelors Degree in Library and Information Science (B.Sc Edu.) from Tai Solarin University of Education, Ogun State and Masters Degree in Library and Information Science (MLIS) from the prestigious University of Ibadan, Nigeria. He is a member of the Nigerian Library Association and a certified librarian of the Library Registration Council of Nigeria. In recognition of his drive for excellence and quest for youth mentoring, Michael won the Sokoto State Honours Award as Best Volunteer for the Millennium Development Goals during his service year and best ENACTUS Mentor. His flair for social entrepreneurship has propelled him into personally executing a number of community impact projects and also coordinated and administered a wide range of same under the auspices of ENACTUS (as Faculty Advisor). These projects have earned his team several awards. His involvement with ENACTUS for over ten years made it possible for him to introduce same to Covenant University in 2016. He is also a volunteer trainer for Microsoft and African Development Bank project – coding for employment program in Nigeria. He has personally founded MeentuP (online mentorship platform for academia, teachers and entrepreneurs), and People's Varsity - a community social change hub that offers individuals in disadvantaged areas access to learning space and information resources. He is presently working on how to make research output of Africans more visible and developed a project is tagged IBILEDATA. Professionally, Michael has pioneered two academic libraries - Iresi College of Technology, Osun State in 2013 and St. Albert The Great Major Seminary, Idow-Offoron, Abeokuta, Ogun State in 2015. Currently, he works at Covenant University as a Librarian/Faculty at the Centre for Learning Resources. As an academic, Michael is well published and has to his credit over 25 publications in highly reputable international journals, conference proceedings as well as book chapters. His research interest revolves around distributed digital libraries, metadata, Knowledge Organization Systems (KOS), Semantic Web technologies, institutional repository, open source software and community and lifelong learning.

Samuel Oluwale Falaki is the current Head, Department of Electrical and Computer Engineering, Afe Babalola University, Ado-Ekiti, Nigeria. He is a Fellow, Nigeria Computer Society, and Computer Professionals Registration Council of Nigeria; Member, Nigeria Society of Engineers, and he is an Engineer registered with the Council for the Regulation of Engineering in Nigeria.

About the Contributors

Liliana Favre is a full professor of Computer Science at Universidad Nacional del Centro de la Provincia de Buenos Aires in Argentina. She is also a researcher of CIC (Comisión de Investigaciones Científicas de la Provincia de Buenos Aires). Her current research interests are focused on model driven development, model driven architecture and formal approaches, mainly on the integration of algebraic techniques with MDA-based processes. She has been involved in several national research projects about formal methods and software engineering methodologies. Currently she is research leader of the Software Technology Group at Universidad Nacional del Centro de la Provincia de Buenos Aires. She has published several book chapters, journal articles and conference papers. She has acted as editor of the book UML and the Unified Process. She is the author of the book Model Driven Architecture for Reverse Engineering Technologies: Strategic Directions and System Evolution.

Ourania-Ioanna Fotopoulou is a family physician/general practitioner. She holds a MD from L' Aquilla University, Italy and a MSc in Primary Health Care from the Aristotle University of Thessaloniki, Greece.

Alexander Fridman graduated from Leningrad Electro-technical Institute in 1975 and worked in Baku (Azerbaijan) for Russian Ship-building Ministry until 1989, when he moved to Apatity (Murmansk region, Russia) and began working for Russian Academy of Sciences (RAS). He got his PhD in 1976, Doctor of Science (Technical) degree in 2001 and Professor degree in 2008. At present he is a Leading Scientific Researcher in the Institute for Informatics and Mathematical Modelling (IIMM) of the Kola Science Centre of RAS and a Professor of the Information Systems Chair in the Kola Branch of the Petrozavodsk State University. Alexander Fridman is a member of the Russian Association for Artificial Intelligence and an expert of the Russian Foundation for Basic Researches. He has 270 scientific publications including 5 monographs, 24 tutorials and 16 certificates for inventions. His main scientific interests are in logical intelligence systems and modelling of hierarchical systems.

Ana Funes is a Professor with tenure at the Departamento de Informática of the Universidad Nacional de San Luis, San Luis, Argentina. She has got a Master degree in Software Engineering and Formal Methods from the Universidad Politécnica de Valencia, Valencia, Spain. She has also been a fellow at the International Institute for Software Technologies of the United Nations University, Macau, where she worked on the integration of formal and semi-formal notations. Her research interests include the combined use of formal and traditional methods for software system specification. She is also interested in Requirement Engineering and Machine Learning. She has published more than fifty articles on these topics in international conference proceedings, books and international journals.

Isabella Gagliardi works at IMATI- CNR since September 2016. She has been working at CNR since 1986. Her major areas of research include Hypermedia Information Retrieval models and methodologies, automatic generation of hypertextual links between text/audio/image, dynamic web based database design and implementation, and clustering algorithms. Recently he has focused his research on the development of multimedia information systems available on the web. On these topics she has several national and international publications, and she has been working in national and international research projects.

Stéphanie Gauttier is an Assistant Professor at Grenoble Ecole de Management. She received her PhD in Information Systems from the University of Nantes (France). She conducts research at the cross-roads between ethics and information systems. Her fields of expertise concern human enhancement, augmented reality, responsible innovation, and Q-methodology.

Beata Gavurova is an expert in finance, financial analysis and financial risk management. She focuses in her research work on issues of measurement and performance management in various sectors, process management and process optimization, strategic and performance benchmarking. Her dominant research area is the development and testing in the management and performance measurement, the evaluation of methodologies and the preparation of an application platform for innovative management and performance measurement with the support of ICT. She led several national projects, has participated in many international projects targeting the innovative applications of ICT in the private and public sector.

Alexander Gegov is currently Reader in Computational Intelligence in the School of Computing. He has been Associate Dean Research for the Faculty of Technology in the past. He has a PhD in Control Systems and a DSc in Intelligent Systems – both from the Bulgarian Academy of Sciences. He has been a recipient of a national award for the best young researcher from the Bulgarian Union of Scientists. He has been Humboldt Guest Researcher at the Universities of Duisburg and Wuppertal in Germany as well as EU Visiting Researcher at the Delft University of Technology in the Netherlands.

James A. George is an experienced CEO, a former executive for Fortune 500 Companies, a consultant for PriceWaterhouseCoopers and ManTech International. He consulted to the US Department of Defense and Health and Human Services in information technology. He served as Academic Director for UC Berkeley Worldwide, developing and instructing course in business management for Asia-nation students. George published hundreds of articles and papers including contributing the Asia Pacific Economic Cooperative Conference on Information Literacy. George was Vice President and Publisher for the Hitchcock Division of the American Broadcasting Companies and Publisher of Infosystems Magazine. George is a graduate of Franklin University and the Ohio State University. Today, George is an independent journalist and author having contributed to CNN and CBS News. Co-Author: Smart Data, Enterprise Performance Automation Strategy © 2010 Wiley Publishing; How to Select an American President © 2017 Archway Publishing; Regenerating America with Sustainable Economics © 2017 Archway Publishing. Author: A President's Manifesto © 2019 All Rights Reserved.

Vyshali Gogi is a VTU Research Scholar at RV College of Engineering®, Bengaluru, Karnataka, India. She holds BSc degree in Computer Application and post graduate degree in "Master of Computer Applications (MCA)" with distinction from University of Mysore, Karnataka, India. Her research area is "Data Mining in Healthcare".

Adán Gómez is Professor of Educational Informatics Department of Educational Informatics (Departamento de Informática Educativa) Universidad de Córdoba.

Patrícia Gonçalves is a graduate in Applied Physics/Mathematics (Astronomy) and master in Computational Methods in Sciences and Engineering. Part of INESC-TEC since October 2016, developing

About the Contributors

work in Network Science, more precisely in multilayer networks. Student of the PhD Program in Engineering and Public Policy.

Sotirios K. Goudos received the B.Sc. degree in Physics in 1991 and the M.Sc. of Postgraduate Studies in Electronics in 1994 both from the Aristotle University of Thessaloniki. In 2001, he received the Ph.D. degree in Physics from the Aristotle University of Thessaloniki and in 2005 the Master in Information Systems from the University of Macedonia, Greece. In 2011, he obtained the Diploma degree in Electrical and Computer Engineering from the Aristotle University of Thessaloniki. From 2004 to 2007, he was a part-time lecturer with the Department of Technology Management, University of Macedonia, Greece. Since 2013, he has been with the Department of Physics, Aristotle University of Thessaloniki. His research interests include antenna and microwave structures design, electromagnetic compatibility of communication systems, evolutionary computation algorithms, and mobile communications. Dr. Goudos is a Senior member of the IEEE, the Greek Physics Society, the Technical Chamber of Greece, and the Greek Computer Society.

M. Govindarajan is currently an Assistant Professor in the Department of Computer Science and Engineering, Annamalai University, Tamil Nadu, India. He received the B.E, M.E and Ph.D Degree in Computer Science and Engineering from Annamalai University, Tamil Nadu, India in 2001, 2005 and 2010 respectively. He did his post-doctoral research in the Department of Computing, Faculty of Engineering and Physical Sciences, University of Surrey, Guildford, Surrey, United Kingdom in 2011 and at CSIR Centre for Mathematical Modelling and Computer Simulation, Bangalore in 2013. He is pursuing Doctor of Science Degree in Computer Science and Engineering at Utkal University, Bhubaneswar, Orissa, India Since 2013. He has visited countries like Czech Republic, Austria, Thailand, United Kingdom (twice), Malaysia, U.S.A (twice), and Singapore. He has presented and published more than 100 papers at Conferences and Journals and also received best paper awards. He has delivered invited talks at various national and international conferences. His current research interests include Data Mining and its applications, Web Mining, Text Mining, and Sentiment Mining. He has completed two major projects as principal investigator and has produced three Ph.Ds. He was the recipient of the Achievement Award for the field in the Conference in Bio-Engineering, Computer Science, Knowledge Mining (2006), Prague, Czech Republic. He received Career Award for Young Teachers (2006), All India Council for Technical Education, New Delhi, India and Young Scientist International Travel Award (2012), Department of Science and Technology, Government of India, New Delhi. He is a Young Scientists awardee under Fast Track Scheme (2013), Department of Science and Technology, Government of India, New Delhi and also granted Young Scientist Fellowship (2013), Tamil Nadu State Council for Science and Technology, Government of Tamil Nadu, Chennai. He also received the Senior Scientist International Travel Award (2016), Department of Science and Technology, Government of India. He has published two book chapters and also applied patent in the area of data mining. He is an active Member of various professional bodies and Editorial Board Member of various conferences and journals. He is IQAC Coordinator and Nodal Officer for data collection, Department of Computer Science and Engineering and also Member of Patent Cell, Annamalai University.

Graciela Hadad has a degree in Information Systems Bachelor at Universidad de Buenos Aires (Argentina, 1983), and has received a Ph.D. in Computer Science at Universidad Nacional de La Plata (Argentina, 2008). She has conducted software developer teams in several Argentine companies during

the past thirty years. She has been teaching Software Engineering in under-graduate courses for the last thirty-two years at different universities. She has been participating in research projects since 1995. Currently, she is a full professor and researcher at Universidad Nacional del Oeste, while also teaching at Universidad Nacional de La Matanza and Universidad de Belgrano. Since 2003, she has been teaching Requirements Engineering in post-graduate courses at different universities. She is supervisor and co-supervisor of Master Thesis and Doctoral Thesis. She currently belongs to a Requirements Engineering research group at Universidad Nacional del Oeste and at Universidad de Belgrano. She has published several papers in conference proceedings, journals, and book chapters along these years.

Osman Hasan received the B.Eng. (Hons.) degree from the N.W.F.P University of Engineering and Technology, Pakistan, in 1997, and the M.Eng. and Ph.D. degrees from Concordia University, Montreal, Canada, in 2001 and 2008, respectively. He served as an ASIC design Engineer from 2001 to 2003 at LSI Logic Corporation in Ottawa, Canada and as a Research Associate at Concordia University, Montreal, Canada, for 18 months after his doctoral degree. Currently, he is an Associate Professor and Principal and Dean at the School of Electrical Engineering and Computer Science, National University of Science and Technology (NUST), Islamabad, Pakistan. He is the founder and director of System Analysis and Verification (SAVe) Lab at NUST, which mainly focuses on the design and formal verification of embedded systems. He has received several awards and distinctions, including the Pakistan's Higher Education Commissions Best University Teacher (2010) and Best Young Researcher Award (2011) and the Presidents gold medal for the best teacher of the University from NUST in 2015. Dr. Hasan is a Senior member of IEEE, member of Association for Automated Reasoning (AAR) and member of the Pakistan Engineering Council (PEC).

Craig Hight is an Associate Professor in Creative Industries at the University of Newcastle, NSW. His research has drawn on documentary theory, software studies, critical data studies and a variety of approaches within the field of audience research. His most recent work explores the nature of documentary culture and practice within digital media platforms. More details on his website: <https://www.newcastle.edu.au/profile/craig-hight>.

Barbara Holland is a native New Yorker with an ongoing quest for knowledge and information from a variety of disciplines. Holds a Bachelor of Arts Degree in Psychology from the City College of New York, a Master's degree in Library Science from Queens College of New York. She currently works at the Brooklyn Public Library as a Senior Librarian and has over 20 years of experience as a librarian and Information Professional. Presented three years at the Georgia International Conference on Information Literacy and The Brooklyn Reading Council each. Numerous Book chapters published with IGI-Global and the Editor of Emerging Trends and The Impacts of Internet of Things and Libraries. Current Editor of Forthcoming book "Libraries During a Global Health Crisis: Response to the COVID-19 Pandemic." As a librarian and Information Professional, it is imperative to keep up with library research and technological trends and provide the information on an ongoing basis.

Wen-Chen Hu received a BE, an ME, an MS, and a PhD, all in Computer Science, from Tamkang University, Taiwan, the National Central University, Taiwan, the University of Iowa, Iowa City, and the University of Florida, Gainesville, in 1984, 1986, 1993, and 1998, respectively. He is currently an associate professor in the School of Electrical Engineering and Computer Science of the University of

About the Contributors

North Dakota, Grand Forks. He was an assistant professor in the Department of Computer Science and Software Engineering at the Auburn University, Alabama, for years. He is the general chairs of about 20 international conferences such as the 2018 International Conference on Engineering, Technology, and Applied Science (ICETA 2018), and associate editors of several journals like Journal of Information Technology Research (JITR). In addition, he has acted more than 100 positions as editors and editorial advisory/review board members of international journals/books, and track/session chairs and program committee members of international conferences. He has also won a couple of awards of best papers, best reviewers, and community services. Dr. Hu has been teaching for more than 20 years at the US universities and over 10 different computer/IT-related courses, and advising/consulting more than 100 graduate students. He has published over 100 articles in refereed journals, conference proceedings, books, and encyclopedias, edited more than 10 books and conference proceedings, was the editor-in-chief of the International Journal of Handheld Computing Research (IJHCR) from 2010 to 2017, and solely authored a book entitled “Internet-enabled handheld devices, computing, and programming: mobile commerce and personal data applications.” He is a member of ACM (Association of the Computing Machinery). His current research interests include handheld/mobile/smartphone/spatial computing, location-based services, web-enabled information system such as search engines and web mining, electronic and mobile commerce systems, and web technologies.

Adamkolo Mohammed Ibrahim is currently pursuing a PhD in mass communication programme at Bayero University, Kano, Nigeria. He received his master’s degree in Development Communication at Universiti Putra Malaysia (UPM) in 2017. In 2007, he had his first degree (BA Mass Communication) at the Department of Mass Communication, University of Maiduguri, Nigeria. Currently, he teaches mass communication at the University of Maiduguri. He conducts research and writes in ICT adoption for development, social media, cyberbullying, cyber terrorism/conflict, gender and ICT, gender and conflict and online shopping. He has published several journal articles, book chapters and a few books. His most recent work explores the impacts of fake news and hate speech in Nigerian democracy and proposes a theoretical model as a fact-checking tool. More details on his most recent works and all his other publications can be accessed on his website: <https://unimaid.academia.edu/AdamkoloMohammedIbrahim>. Malam Adamkolo is currently serving as a co-researcher in a research project by The Kukah Centre, Abuja, Nigeria. The proposed title of the research is: “Engaging Local Communities for Peacebuilding, Social Cohesion, Preventing and Countering Violent Extremism in Nigeria’s northeast”. Adamkolo has received Publons Top Reviewer Award in 2018 (for being among the top 1% global peer reviewers in Psychiatry/Psychology). In 2017, Elsevier had awarded him a certificate of outstanding peer review with one of Elsevier’s prestigious journals, Computers in Human Behaviour (CHB) which he reviews for; he also reviews for Emerald’s Journal of Systems and Information Technology (JSIT) and several other journals. Much earlier, from 2000 to 2010, he worked as a broadcast journalist in Yobe Broadcasting Corporation (YBC) Damaturu, and from 2008 to 2010 was deployed to Sahel FM (formerly Pride FM, a subsidiary of YBC Damaturu as DJ-cum-producer/presenter/journalist). From 2008 to 2010, he worked as YBC’s focal person on UNICEF and Partnership for the Revival of Routine Immunisation in Northern Nigeria-Maternal, New-born and Child Health (PRRINN-MNCH). From September to October 2018, he served as a consultant to ManienDanniels (West Africa Ltd.) and MNCH2 programme.

Promise Ifeoma Ilo is the University Librarian, PAMO University of Medical Sciences, Port Harcourt, Nigeria, and the immediate past University Librarian, Covenant University, Ota. Dr. Ilo ob-

tained her Masters and PhD degrees in Library and Information Science from the University of Nigeria Nsukka in (2000) and (2017) respectively. She has worked in both academic and school libraries. Dr Ilo has above forty five publications in reputable local and international journals. She was the Chief Editor, Covenant Journal of Library and Information Science (CJLIS), an online journal of the Centre for Learning Resources, Covenant University Ota. Promise Ilo won the ALCTS Training Award of the American Library Association for librarians (2019). She also holds the awards for the best graduating student (Dept. of Library Science) as well as the best graduating student, School of Education, Federal College of Education Eha-Amufu, (1989). Her research interests are Disaster management in libraries, Information and communication technology in libraries, Health information awareness among rural women, Library user education, among others. Dr Ilo is a member of the Gideons International, Nigeria. She has rendered various services on the platform of the Church Action Committee on HIV/AIDS (CACA) in the Diocese of Lagos West.

Roland Izuagbe works as a Serials Librarian in Center for Learning Resources (The University Library), Covenant University, Ota, Nigeria. Roland holds a Bachelor of Science (BSc) in library and information science from Ambrose Alli University (AAU) Ekpoma, and a master degree in library and information studies (MLIS) from the University of Ibadan, Ibadan. He has published in reputable journals like Library and Information Science Research (LISR), The Journal of Academic Librarianship (JACALIB), International Journal of Disaster Risk Reduction (IJDRR), Library Review (Now, Global Knowledge, Memory and Communication), Journal of Cases on Information Technology (JCIT), among others. His research interests include information and communication technology (ICT), information systems acceptance/adoption, electronic information resources, disaster management in libraries, social media use in libraries and organisational science.

Raheleh Jafari received a B.S. degree in pure mathematics from Islamic Azad University in Shabestar, Iran in 2008 and M.S. degree in Applied Mathematics from Islamic Azad University in Arak, in 2010. She received Ph.D. degree in Automatic Control from National Polytechnic Institute (CINVESTAV-IPN), Mexico City, Mexico, in 2017. In 2017, she worked as a post-doctoral research fellow at the Department of Information and Communication Technology, University of Agder, Grimstad, Norway. Currently, she is working as University Academic Fellow at the School of design, university of Leeds, Leeds, United Kingdom. Her research interests include Artificial intelligence, Fuzzy logic, Robotics and Automation.

Swati Jagdale has completed her B. Pharm. (1998), M. Pharm. (2000) from Pune University and Ph. D. (2009) from Shivaji University Kolhapur. She is presently working as Professor at School of Pharmacy, Dr. Vishwanath Karad World Peace University, Pune. She has published more than 80 research articles in reputed National and International Journals. She has written 5 books and 5 Book chapters. She had filed 3 Indian patents. She had completed 2 minor research projects of Savitribai Phule Pune University (4.9 Lakhs). Presently she is working on research project by Council of Scientific and Industrial Research (CSIR) (Amount 25 Lakh) and AICTE project under MODROB scheme (Amount 17.22 Lakhs). She has guided 61 M.Pharm students and 01 Ph.D. student. Presently 04 students of M. Pharm and 07 students of Ph.D. are working on their project under her guidance. She is also working as member, Board of Studies under Science and Technology for Faculty of Pharmaceutics in Savitribai Phule Pune University from 2019. She has awarded as Award of Excellence in Research in 2019 by DK International Research Foundation, Best Professor In Pharmaceutics Studies by 11th DNA Innovative Education Leadership

About the Contributors

Awards in 2019, Best Teacher Award 2017-18 – Professional Category (Urban) by Savitribai Phule Pune University in 2018, SHIKSHAK SHRI AWARD at National Teacher conference and Presentation by Antarrashtriya Samrasta Manch, Jaipur in 2017, DR. G.R. EKBOTE WOMEN PHARMACIST AWARD of MAHA-APTICON-2016 & PHARMA AWARD-2016 by Association of Pharmaceutical Teachers of India, Maharashtra State in 2016, was nominated and received appreciation trophy for SKB YOUNG PHARMACY TEACHER OF THE YEAR AWARD of MAHA-APTICON-2016 & PHARMA AWARD-2016 by Association of Pharmaceutical Teachers of India, Maharashtra State in 2016, Ideal Teacher award by MAEER's Maharashtra Institute of Technology in 2011. Her research article on Formulation and Evaluation of Gastroretentive Drug Delivery System of Propranolol Hydrochloride was one of the top 5 downloaded articles in AAPS PharmSciTech in 2012. She had also worked as member Board of Studies for Faculty of Pharmaceutics of University of Pune in 2011-15.

Jennifer Joe currently works at the University of Toledo, where she is the Undergraduate Engagement Librarian. Previously, she was the Owensboro Campus Librarian for Western Kentucky University. She received her MLS from Indiana University-Bloomington in 2010, and her MA in Sociology from Western Kentucky University in 2011. Her research interests include community outreach, collection development, information literacy, and the integration of technology into libraries and library practices, with special emphasis on social media. She has previously been published in the Encyclopedia of Information Science and Technology, Fourth Edition (IGI Global 2017) and is co-editing a book entitled Social Media for Communication and Instruction in Academic Libraries, which was published by IGI-Global in March 2019.

Marianna Kapari holds a MSc in Human Computer Interaction from Uppsala University, Sweden, a BSc degree in Computer Science from London Metropolitan University, UK, and a BA in Communication from the American College of Greece. Marianna joined INFOLYSiS as Frontend and digital media developer with experience in web technologies (HTML, CSS, PHP, Javascript, MySQL), prototyping tools (InVision, Balsamiq Mockups, Axure, WireframeSketcher), video editing (Adobe Premier, Ulead VideoStudio, Cyberlink Power Director) and software design tools with UML. Her research interests include IoT interoperability and IoT GW frontends with emphasis on novel HCI technologies, such as Chatbots with Machine Learning techniques.

Shogo Kato is an Associate Professor in the School of Arts and Sciences, Tokyo Woman's Christian University in Japan. He earned a Ph.D. from Tokyo Institute of Technology in 2005. He is particularly interested in the emotional aspects in virtual community, such as Internet bullying.

Yuuki Kato is an Associate Professor at Sagami Women's University, Faculty of Arts and Sciences in Japan. He earned a Ph.D. from Tokyo Institute of Technology in 2005. His general research interests include educational technology, the application of behavior science, psychology, and information and communication technology to educational scenes.

Elaine Khoo is a senior research fellow at the Wilf Malcolm Institute of Educational Research (WMIER) at the University of Waikato, New Zealand. Elaine's research interests include information and communication technology (ICT) and digital pedagogies, e-learning/online learning with a particu-

lar interest in online learning communities, participatory learning cultures and collaborative research contexts. More details on her website: <http://www.waikato.ac.nz/staff-profiles/people/ekhoo>.

George M. Korres holds a doctorate in Economic Sciences (Economics of Innovation) from University of London (QMW) and an M.Sc from Essex University. He is currently a visiting fellow from University of Newcastle, Centre from Urban Regional & Development Studies, (CURDS), School of Geography, Sociology and Politics, and also an associate professor at the University of the Aegean, Department of Geography. He was visiting scholar at the University of Leeds during 2006-2007. Over the last 10 years, during both his academic and professional career, he has gained an in depth experience in the fields of economics, business and politics in the area of European Economics and Innovation Systems. His main areas of interest and specialisation include: European Integration, Social Policy and Social Inclusion, Economic and Innovation Policies, EU enlargement and the Euro-Mediterranean partnership. He has collaborated with many European universities, Institutions, NGOs as well as academia. George Korres has also been involved in various trans-European and international projects and he has published widely in this area in many International Journals, such as *Applied Econometrics*, *Regional and Sectoral Economic Studies*, *Southwestern Economic Review*, *Pensions*, *Sage*, *Management Sciences* and *Regional Development* etc, also he has published a number of books with international publishers, such as MacMillan-Palgrave Press, Springer, Edward and Elgar, Ashgate Publishers and Nova (New York) Publishers.

Maximiliano E. Korstanje is editor in chief of *International Journal of Safety and Security in Tourism* (UP Argentina) and *International Journal of Cyber Warfare and Terrorism* (IGI-GlobalUS). With more than 700 published papers and 25 books, Korstanje was awarded as Outstanding Reviewer 2012. *International Journal of Disaster Resilience in the Built Environment*. University of Salford, UK, Outstanding Reviewer 2013. *Journal of Place Management and Development*. Institute of Place, Manchester Metropolitan University, UK and Reviewer Certificate of Acknowledgement 2014. *International Journal of Contemporary Hospitality Management* (IJCHM), University of Central Florida, US. Now he co-edits almost 10 specialized journals in such themes as human rights, mobility, tourism and terrorism. Korstanje is subject to biographical records for *Marquis Who's Who in the World* since 2009. He had nominated to 5 honorary doctorates for his contribution in the study of the effects of terrorism in tourism. In 2015 he was awarded as Visiting Research Fellow at School of Sociology and Social Policy, University of Leeds, UK and Visiting Professor at University of La Habana Cuba 2016.

Aleksandra Kostić-Ljubisavljević was born 1974. in Belgrade. She received her B.Sc. (1999), M.Sc. (2005) and Ph.D (2011) degrees in telecommunication traffic engineering at the University of Belgrade - Faculty for Transport and Traffic Engineering, where she is currently employed as Associate Professor. She published more than 140 papers regarding her scientific area of interest: economical and technical aspects of telecommunication networks integration, optical communication networks, visible light communication, intelligent transportation systems (communication systems), and telecommunication network regulation.

Harilaos Koumaras was born in Athens, Greece in 1980. He received his BSc degree in Physics in 2002 from the University of Athens, Physics Department, his MSc in Electronic Automation and Information Systems in 2004, being scholar of the non-profit organization Alexander S. Onassis, from the

About the Contributors

University of Athens, Computer Science Department and his PhD in 2007 at Computer Science from the University of Athens, Computer Science Department, having granted the four-year scholarship of National Centre of Scientific Research “Demokritos”. He has received twice the Greek State Foundations (IKY) scholarship during the academic years 2000-01 and 2003-04. He has also granted with honors the classical piano and harmony degrees from the classical music department of Attiko Conservatory. Since 2018, Dr. Koumaras is an Assistant Research Professor at NCSR “Demokritos”.

Vaios Koumaras received his BSc degree in Business Administration with major in Computer Information Systems from the American College of Greece and his MBA in IT Project Management from the City University, USA. Since 1997, he has worked in several positions as Computer Analyst and Software Developer, participating in major IT projects. Currently, he is the managing director of INFOLYSIS P.C., with participation and collaboration in R&D IT projects of numerous companies worldwide, mainly in the development of chatbot apps and the applicability of IoT on top of virtualized infrastructures mainly in the shipping sector for optimizing the cargo containers embarking process and choosing the optimal route, subject to the load and the weather/sea factors. Moreover, Mr. Koumaras is specialized in the development of chatbots over messaging platforms and in the IoT interoperability provision, researching also the applicability with novel SDN/NFV techniques.

Jan Krmela is a head of Department of Numerical Methods and Computational Modelling. Research areas: 1. Computational modeling and tests of composites with a rubber (an elastomer) matrix such as tire casings, especially with focus on strain-stress states and modal analysis and computational modeling of composites after the degradation processes, tire-road interaction and vehicle parts; 2. Tests of tires on static and dynamic test machines with the pressure footprint analyses of contact footprints between tires and a plane road or a bump and also prediction of radial stiffness of tires; 3. Low cyclic loading tests of composites with textiles on a test machine with a video extensometer and static tests of composites with planning of tests with a design of geometric parameters of test samples and test conditions for testing of tire casing parts; 4. Determination of material parameters that can be used as input data into computational models; Microscopic observation of interface bonds between steel and textile cords and an elastomer; 5. 3D printing of technical objects.

Matus Kubak focuses in his scientific and research activities on the use of parametric and non-parametric quantitative methods on economic issues. He was also team member of teams dealing with experimental economics and agent-based modeling, where he participated mainly as a data miner.

Boris Kulik graduated from Leningrad Mining Institute and worked for the USSR Ministry of Geology from 1971 to 1989 in automation of drilling control. Then he took up research on logic, mathematics and artificial intelligence and got his PhD in 1996. Since 1997 Boris Kulik has worked in St.-Petersburg Institute of Problems in Machine Science of the Russian Academy of Sciences. He got his Doctor of Science (Physics and Mathematics) degree in 2008. He has published 120 scientific papers including 6 monographs.

Harendra Kumar is an Assistant Professor in the Department of Mathematics & Statistics, Gurukula Kangari Vishwavidyalaya Haridwar-Uttarakhand (India). He obtained his Master of Science in 2003 from I.I.T Roorkee and Ph.D. from Gurukula Kangari Vishwavidyalaya in 2008. He has qualified NET

(UGCJRF)- Dec.2003, NET(CSIR-JRF)-June 2005 and GATE-2004. He has published several research papers in National and International Journals in the field of Operation Research & Distributed Real Time System. He has more than 10 years teaching experience and has written three books for undergraduate & postgraduate students. He has authored several chapters for edited books. Dr. Kumar was invited to chair several international conference/workshop programs and sessions. He served in the program committees of several international conferences.

Marcus Leaning is Professor of Digital Media Education in the School of Media and Film at the University of Winchester in the UK.

Viviana Ledesma has a degree in Computer Engineer at Universidad Nacional de La Matanza in 2004. In 2019 she presented her master's thesis, which is about the definition of a mechanism for the dynamic adaptation of a requirements engineering process according to situational factors. She has participated in different Requirements Engineering research projects since 2013. She has published several papers in conference proceedings and book chapters along these years. She works as an assistant, teaching software design at Universidad Nacional de La Matanza since 2004.

Wanbil Lee is a cyberethics evangelist. He is also Principal, Wanbil & Associates; Director, Flynn Institute as well as Founder and President, The Computer Ethics Society; Co-founder & Life Fellow, The Hong Kong Computer Society; Advisory Board Member, European Centre of eCommerce & Internet Law; and Member of Nous Global International Experts Network. Dr Lee sits on several professional/learned societies and government committees. Prof Lee has held tenured and adjunct academic posts including that of Foundation Head, Department of Computing Studies, Lingnan University, Hong Kong, and Hon. Research Associate at the Computer Science Centre for Information Security & Cryptography, Hong Kong University. In addition, he held technical line and staff positions in the Australian Government and international banks. He was awarded a DBA for the dissertation on the effect of Semi-intelligent Risk-analytic Audit. His field of interest spans Computer Auditing and Ethical Computing with a current focus on techno-ethical issues: data protection & cybersecurity.

Jose Luis Lo Huang is a Computer Engineer graduated from Simón Bolívar University in Venezuela. He is specialized in Database Design and Administration, Network Services and Information Security. He has over 5 years experience in Unix / Linux Systems Administration and as instructor and developer of open source software, many of them working in the Computer Teaching Laboratory in the university. During his university period, he worked in areas like Artificial Intelligence, Robotic and Wireless Networks. Also, he was part of the university volunteer fire department, the chess group, the athletics club and co-founder of the Rubik's cube solvers club. He is member of IEEE, ACM and ISOC. Now, he is working at Oracle Corporation as Senior Consultant.

Shen Lu is a PhD candidate in Computer Science at University of South Florida. Her research interests include database systems, distributed computing, and GPU computing, especially in deep learning. Shen received BS and MS degrees in Computer Science from Tsinghua University, China. She has won Microsoft Innovation Cup Student Software Competition at the first place, and received Best Paper Awards for three times. Shen is the founder and CEO of Soft Challenge LLC which works on software

About the Contributors

development, business solutions, and web applications. At Soft Challenge, Shen has lead and conducted research for both academic and industrial customers in commercializing research products.

Sabrina Ching Yuen Luk is Assistant Professor in Public Policy and Global Affairs. She holds both Bachelor of Social Science (First Class Honours) and M.Phil from the Chinese University of Hong Kong and Ph.D. from the University of Birmingham, the United Kingdom. Dr. Luk's research interests lie broadly in aging and health care reforms, e-government and governance in Asia, digital health and cyber security, public policy analysis and China studies. She was the Highly Commended Award Winner of the 2013 Emerald/EFMD Outstanding Doctoral Research Awards in the Healthcare Management Category. She has published three books, including *Health Insurance Reforms in Asia* (New York: Routledge, 2014), *The Logic of Chinese Politics: Cores, Peripheries and Peaceful Rising* (UK: Edward Elgar Publishing Ltd, 2016) (with Peter Preston) and *Financing Health Care in China: Towards Universal Health Insurance* (New York: Routledge, 2017).

Divyaprabha M. is a student at Thiagarajar College of Engineering. Her research area include Network and Information Security.

Thangavel M. is an Assistant Professor presently working in the Department of Information Technology at Thiagarajar college of Engineering, Madurai. He presently holds 6 years of Teaching and Research experience in Thiagarajar college of Engineering, Madurai and 2 years of Teaching and Research experience in Madras Institute of Technology, Anna University - Chennai. He graduated as a B.E. Computer Science and Engineering from M.A.M College of Engineering, Trichy (Anna University - Chennai) and as an M.E. Computer Science and Engineering from J.J. College of Engineering and Technology, Trichy (Anna University - Chennai) and Pursuing his PhD from Madras Institute of Technology, Chennai under Anna University - Chennai. He is a Gold Medalist in UG and Anna University - First Rank Holder with Gold Medal in PG. His specialization is Cloud Computing, and Information Security. His Areas of Interest include DNA Cryptography, Ethical Hacking, Compiler Design, Computer Networks, Data Structures and High Performance Computing. He has published 8 articles in International Journals, 12 book chapters in International Publishers, 22 in the proceedings of International Conferences and 3 in the proceedings of national conferences /seminars. He has attended 91 Workshops / FDPs/Conferences in various Higher Learning Institutes like IIT, Anna University. He has organized 48 Workshops / FDPs /Contests/Industry based courses over the past 8 years of experience. He has been a delegate for Cyber Week 2017 organized by Tel Aviv University, Israel. He has been recognized by IIT Bombay; SAP CSR as SAP Award of Excellence with cash reward of Rs.5000/- for the best Participation in IITBombayX: FDP ICT001x Use of ICT in Education for Online and Blended Learning. He shows interest in student counseling, in motivating for better placements and in helping them design value-based life-style.

Vijayalakshmi M.N. is an Associate Professor in Department of Master of Computer Applications, RV College of Engineering®, Bengaluru, Karnataka, India. She possesses degree in M.C.A and M.Phil. She has received her Ph.D. degree in 2010 and has been honoured by ISTE, R.V.C.E chapter in 2011 for the award of PhD in Computer Science. Her area of interest is data mining and image processing. She has 22 years of teaching experience and has been honoured by Rastriya Shikshana Samiti Trust in the year 2012 for her exemplary contribution for teaching. She has been awarded as "Best Indian Citizen Gold Medal Award" by Global Economic Progress Research Association on 26th January 2016 for

Individual Achievement and National Development. She has successfully completed a research project funded by Computer Society of India as principal investigator. She has presented and published more than 55 papers at Conferences and Journals. She has received “Outstanding Scientist Award” by Venus International Foundation in 2015. She has delivered invited talks at various national and international conferences. She has guided 100 projects till now. She has 4 book chapter publications. She is member of various professional bodies.

Martin Maier received the MSc and PhD degrees (both with distinctions) from the Technical University of Berlin, Germany, in 1998 and 2003, respectively. He is a full professor with the Institut National de la Recherche Scientifique (INRS), Montreal, Canada. In the summer of 2003 he was a postdoc fellow at the Massachusetts Institute of Technology (MIT), Cambridge. He was a visiting professor at Stanford University, Stanford, from October 2006 to March 2007. Further, he was a co-recipient of the 2009 IEEE Communications Society Best Tutorial Paper Award. He was a Marie Curie IIF fellow of the European Commission from March 2014 to February 2015. In March 2017, he received the Friedrich Wilhelm Bessel Research Award from the Alexander von Humboldt (AvH) Foundation in recognition of his accomplishments in research on FiWi enhanced networks. In May 2017, he was also awarded as one of the three most promising scientists in the category “Contribution to a better society” of the Marie Skłodowska-Curie Actions (MSCA) 2017 Prize of the European Commission. He is the founder and creative director of the Optical Zeitgeist Laboratory (www.zeitgeistlab.ca). He is a senior member of the IEEE.

Abhishek Majumder received his B.E. degree in Computer Science & Engineering from National Institute of Technology, Agartala and M.Tech. degree in Information Technology from Tezpur University, Assam in 2006 and 2008, respectively. He has completed PhD from the Department of Computer Science & Engineering, Assam University, Assam in 2018. He is currently working as an Assistant Professor in the Department of Computer Science & Engineering, Tripura University (A Central University), Suryamaninagar, India. His areas of interest are Wireless Network and Cloud Computing.

Benedita Malheiro holds a PhD. and a MSc. in Electrical and Computers Engineering and a five year graduation degree in Electrical Engineering from the University of Porto (Faculty of Engineering). She is currently an Adjunct Professor at the Electrical Engineering Department of the School of Engineering - Instituto Superior de Engenharia do Porto - of the Polytechnic Institute of Porto. As a researcher, she is specialized in problems of a distributed, dynamic and decentralized nature. Her areas of interest include data science, multi-agent systems, intelligent software agents, conflict resolution, belief revision, personalisation, context-awareness, location-based services, recommendation, cloud computing and engineering education.

Theodora A. Maniou is a faculty member in the Department of Social & Political Sciences, University of Cyprus. She holds a PhD in Journalism (School of Journalism & Mass Media, Aristotle University, Greece). Her research includes a monograph regarding broadcast journalism in Cyprus and several articles in international journals regarding journalism and media studies.

Stephen W. Marshall, Ph.D., is a digital marketing and media expert. He is an award-winning professor consulting for brands such as Adobe, Coca-Cola, Texas Pete and Pal’s Sudden Service. He

About the Contributors

received his doctoral degree from the University of Florida and is Chair of the Department of Media & Communication. Dr. Marshall works for Adobe as an industry trainer/expert helping Fortune 500s around the world create amazing digital customer experiences.

Alexander Maz-Machado has a degree in Mathematics and Physics from Tolima University, a Ph.D. in Mathematical Sciences from the University of Granada. He is Associate Professor of the Department of Mathematics of the University of Córdoba, Spain.

Nigel McKelvey (Ed.D., MSc., BSc., PGCE, MICS) is a lecturer in Computing at the Letterkenny Institute of Technology and specialises in teaching secure programming techniques at both undergraduate and postgraduate level. Other areas of interest include ethical gaming, performance based programming and digital forensics. Nigel is an advocate of CoderDojos and encourages community programming initiatives.

Maria P. Michailidis holds a Bachelor degree in Business Administration-Management, two Master degrees in Community-Social Psychology and Clinical Psychology and a Doctorate degree of Education in Educational Leadership, from the University of Massachusetts, Lowell Massachusetts, USA and the University of Indianapolis, Indiana, USA. She is also a Client-Centered Psychotherapist with a Diploma in Psychotherapy of The Person-Centered Approach (PCA). Dr Michailidis is a Professor and the former Dean of the School of Business at the University of Nicosia, Cyprus and a member of the Management and MIS Department. In the past, she served as the Head of the Education Department of the University of Nicosia and Intercollege. Professor Maria Michailidis is the author of several book chapters, journal articles and editor of several books. She has a long industrial experience as she worked in the United States and Cyprus, as well as teaching experience from teaching in higher education both in the United States and Cyprus. She is a researcher and a regular invited speaker and presenter at international conferences. Most of her research work has been supported by grants; she has also been a research partner in European Union projects such as Leonardo da Vinci; Socrates/Erasmus Thematic Networks, Grundtvig Multilateral Projects and COST actions. Her research interests include occupational health, illness and wellness, gender and intercultural studies, unemployment issues, working women and stress, occupational stress, women entrepreneurs. She is a board member of the A. G. Leventis Scholars Association and also of the Elpida Foundation for Children with Cancer and Leukemia.

Branka Mikavica received her B.Sc. (2011), M.Sc. (2013) and Ph.D. (2019) degrees in telecommunication traffic engineering from the University of Belgrade – Faculty of Transport and Traffic Engineering, where she is currently assistant professor. As author or coauthor, she published more than 40 papers in national and international journals, books and conferences. Her research interests include networks integration, cloud computing and elastic optical networking.

Mohammad Izzuddin Mohammed Jamil is currently undertaking a PhD course at Universiti Brunei Darussalam. He received his Bachelor's Degree in Business Administration at Coventry University and Master's Degree in Management at Universiti Brunei Darussalam. He is an O Level and A Level Tutor, teaching Business, Accounting, Economics and Commerce. His interests include lifelong pursuit of knowledge, sharing those knowledges, involvement in the world of research and academia, and aspires to become an entrepreneur on multiple portfolios. His research interests include topics related

to Entrepreneurship, Innovation, Digital Literacy, Strategy, Organisational Theory, Investment, SMEs, Internet of Things, E-Commerce and Career Choice. He is also proficient in IT skills that is relevant for the sustainability of enterprises such as Computer-Aided Design for the designing of new products, Graphic Design to devise advertisements, Web Design for the creation and maintenance of websites, as well as Database Management.

Md. Awal Hossain Mollah is teaching at the University of Rajshahi, Bangladesh for the last 16 years in Public Administration. He is working on various issues of politics and governance in the context of Bangladesh and South Asia. He has published two chapters in “Global Encyclopedia of Public Administration, Public Policy and Governance” and one chapter in “Encyclopedia of Gerontology and Population Aging”. Besides, he has a number of peer reviewed journal articles published by Sage, Springer, Routledge, Emerald, and Palgrave including a book and some book chapters.

José Augusto Monteiro has MSc on Information Management from ‘FEUP - Faculdade de Engenharia da Universidade do Porto’ (2009). He is MCP - Microsoft Certified Professional, and has ‘CAP - Certificado de Aptidão Pedagógica’ from ‘IEFP - Instituto de Emprego e Formação Profissional’. He has started his professional career on mechatronics and industrial equipment at Cimertex SA, has served in Portuguese Air Force as an operational in Radar Maintenance area, and it has been working in IT Systems area and office automation at ‘Beltrão Coelho (Porto)’ over 10 years. Since 2004, he teaches and researches at ‘ISPGaya - Instituto Superior Politécnico Gaya’. Also, it plays the roles of the coordinator of the Course of Management of Networks and Computer Systems and it is responsible for the IT Systems that support academic activities. Now, he is a PhD candidate on Science and Web Technology at Open University in Portugal.

Ana S. Moura is a full-time researcher at the University of Porto, has authored or co-authored several books for more than a decade and takes a keen interest in such various areas as Computational Chemistry, Biomedicine, Social Sciences, and Physics.

Debapriya Mukherjee is an M.Tech student in the Dept. of Radio Physics and Electronics, University of Calcutta, India. She received her B.Tech degree in Radio Physics and Electronics in the year 2018.

Abdullah Murrar is a PhD Researcher at Indiana University of Pennsylvania in USA. Mr. Murrar has two master degrees: the first master is in Business Administration, and the second master is in Strategic Planning. He published about 10 papers in international journals. Subjects are in managing the staff who work in information technology sector, evaluating the sustainability of water sector, and developing the financial markets. Mr. Murrar has total experience about 20 years in software development management, financial management, and multidisciplinary research. He has extensive experience in management of the software development such as gathering business requirements from the end users, preparing functional design and prototyping, estimating the budgetary cost and managing the software development team. Mr. Murrar worked with international donors such as World Bank, GIZ, Cesvi, and USAID. He has experience in financial management of projects such, financial planning, financial reporting, and financial system implementation. He was speaker about financial sustainability and economic development in local radios, local and regional conferences.

About the Contributors

Ambika Nagaraj has completed her MCA in the year 2001 and M.Phil in the year 2008. She has completed her Ph.D. from Bharathiar University, Coimbatore. She has 12 years of teaching experience. She has published a significant amount of papers in chapters in books, national/ International conference papers and Journals. Presently she is working as a faculty in the computer science department at SSMRV degree college.

Rajit Nair has done a lot of research in the area of Machine Learning, IoT and Blockchain. He is working in Jagran Lakecity University as an Assistant Professor which is located at India. He has published many papers and chapters in various international journals and conferences. He is having more than 13 years of academic experience in the field of Computer Science & Engineering and also working as a reviewer of reputed International journals. He also received many awards from various organizations for contribution in the field of academics. Currently he is working on different project which are based on IoT and machine learning.

Ritu Narang is Assistant Professor Stage III at the Department of Business Administration, University of Lucknow. She has done her Ph. D. and D.Lit. in Business Administration and was first in the order of merit in Business Administration. She was awarded 'The Best Research' Award among the Teachers by the University of Lucknow in 2010. Two of her research papers have been awarded 'The Best Research Paper' in International Conferences including one organized by Oxford Business School. Twice she has been a Senior Distinguished Fellow at Hanken School of Economics, Helsinki and once at Tianjin University, China. Dr. Narang has successfully completed two Major Research Projects sponsored by University Grants Commission, New Delhi. Her papers have been presented at various national and international conferences including Academy of Marketing Science World Marketing Conference, POMS Annual Conference, Centre for Marketing in Emerging Economies (Annual Conference of the Emerging Markets Conference Board), India Academy of Management, Conference on Retailing in Asia Pacific (The Oxford Institute of Retail Management), American Marketing Association's Services Special Interest Group International Conference, etc. Dr. Narang has several publications in various international journals such as International Review of Retail, Distribution and Consumer Research, International Journal of Case Studies in Management, International Journal of Health Care Quality Assurance, Clinical Governance: An International Journal, Young Consumer, International Journal of Management in Education, Quality Assurance in Education, Vikalpa, etc. She has done Indian adaptation of a book on Organization Behaviour published by Pearson Publishers. She has published several chapters in national and international books. Dr. Narang has also been involved in delivering talks to managers of public and private sector organizations.

Sabyasachi Nayak is a Social Development Professional for the last ten years. Currently, he is working as a Counselor with the Confederation of Indian Industry. In his current position, he is extensively involved in coordinating with Government, industry and other stakeholders in addressing challenges with respect to water management.

Nicholas Nechval (Ph.D. in Automatic Control and Systems Engineering, and Dr.Habil.Sc. in Radio Engineering) is a Professor in the Department of Mathematics at the Baltic International Academy, Riga, Latvia, and Principal Investigator in the BVEF Research Institute at the University of Latvia, Riga, Latvia. Before his current position, from 1993 to 1999, Dr. Nechval was a Professor of Mathematics and

Computer Science and the Head of the Research Laboratory at the Riga Aviation University. From 1999 to 2014, Dr. Nechval was a Professor and Head (Statistics Department and EVF Research Institute) at the University of Latvia, Riga, Latvia. He was also a Principal Investigator in the Institute of Mathematics and Computer Science at the University of Latvia. Dr. Nechval, in 1991, was awarded a Silver Medal of the Exhibition Committee (Moscow, Russia) for his research on the problem of Prevention of Collisions between Aircraft and Birds. His research interests include mathematics, econometrics, stochastic processes, pattern recognition, digital radar signal processing, operations research, statistical decision theory, adaptive control, and mechanical engineering. Professor Nechval has authored and coauthored more than 455 papers and 9 books, including the book: *Aircraft Protection from Birds* (Moscow: Russian Academy of Science, 2007) coauthored with V. D. Il'yichev (Academician of the Russian Academy of Science), and the book: *Improved Decisions in Statistics* (Riga: Izglitibas Soli, 2004) coauthored with Prof. E. K. Vasermanis (University of Latvia). This book was awarded the “2004 Best Publication Award” by the Baltic Operations Research Society. Dr. Nechval is also an Editorial Board Member of several international journals.

Isaiah Oke holds a PhD degree in Civil Engineering. His main research Interest is in water Engineering. He has published a number of articles in reputable journals and Conference Proceedings. He is an academic in the Department of Civil Engineering, Obafemi Awolowo University, Ile-Ife, Nigeria.

Fehintola Olumuyiwa is a Senior Lecturer at Department at Adeyemi College of Education.

María-Dolores Olvera-Lobo is a Doctor in Documentation, Full Professor at the Department of Information and Communication at the University of Granada (Spain) and teacher at the Faculties of Communication and Documentation, and Translation and Interpreting. She has taught courses in PhD, Master's and Postgraduate programmes at various universities. She has led research groups and projects, and teaching innovation projects. She has participated in a number of international conferences. She has written and co-authored books, chapters and dozens of articles published in prestigious specialised magazines.

Aanuoluwapo Oluwaseun Omolade-Lawal is a Process Analyst at the University College Hospital, Ibadan, Nigeria. She holds a B.Sc in Computer Science from the then University of Ado-Ekiti (now Ekiti State University, Ado-Ekiti) and a Master of Information Science (M.Inf.Sc) from the Africa Regional Centre for Information Science, University of Ibadan where she is currently undertaking her doctoral research in Information Systems.

Ruslan Ostroha is a member of Processes and Equipment of Chemical and Petroleum-Refineries Department. Research areas: 1. Experimental and analytical study of hydromechanical and heat-mass transfer processes in chemical technology. 2. Studying hydrodynamics of flows with regard to their effect on thermal and physical characteristics of the suspended layer of particles. 3. Development of new types of heat-mass transfer equipment with the use of sectioning to create different conditions for the particle in the device.

Sarvesh Pandey received his Master degree from Computer Science and Engineering Department, Madan Mohan Malaviya University of Technology, Gorakhpur, India in year 2014. Presently he is

About the Contributors

working as a Senior Research Fellow (PhD Research Scholar) in Computer Science and Engineering Department, Madan Mohan Malaviya University of Technology, Gorakhpur, India. His area of interest includes Real Time Systems, Distributed Real Time Database Systems, Mobile Distributed Real Time Database Systems, Database Replication, and Cloud Service Trustworthiness. He has published more than 10 research papers in National & International conferences, Journals and Books. He is pursuing his PhD in Computer Science & Engineering. He is a reviewer of a few reputed SCI Journals.

Lambrini Papadopoulou holds a PhD in Journalism (Department of Communication, Media & Culture of Panteion University, Greece). Her thesis was concerned with new business models for journalism. She currently teaches Web journalism in Panteion University while practicing journalism in Greece. Her research has been published, among others, in Journalism Studies and Journalism Practice.

Angeliki Papaioannou studied Physics and Computer Science at the National and Kapodistrian University of Athens and received her B.Sc. in Physics in 2003 and her M.Sc. in Electronics and Automation with specialization in Informatics and Information Systems in 2010. Angeliki has worked for LogicDIS as Software Engineer and later as Product Manager of Securities ERP. In 2017, she joined as an associate software engineer INFOLYSiS, developing various IoT applications of INFOLYSiS portfolio, using Arduino nodes, Zigbee, web, mobile and Java tools. Her current research interests include interoperability IoT mapping functions for heterogeneous IoT platforms, SDN, NFV, Cloud Computing, IoT infrastructures, Monitoring systems and web/mobile applications.

Satyam Paul is a researcher in the Department of Mechanical Engineering, Örebro University. He earned his PhD from the Department of Automatic Control, Center for Research and Advanced Studies of the National Polytechnic Institute (CINVESTAV-IPN), Mexico City, Mexico. He has a Master degree in the field of Mechatronics from VIT University, India and a Bachelor degree in Mechanical Engineering from National Institute of Technology, India. His research area includes control systems, intelligent techniques, vibration control and predictive maintenance.

Yuri Pavlov is associate professor in the Institute of Information and Communication Technologies, Bulgarian Academy of Sciences. He received DUES from Paris VI - France, MSc degree in Automation from Technical University of Sofia and holds PhDs from the BAS. He has publications in: Proceedings of Bulgarian Academy of Sciences, Bioautomation, EJOR, E-learning III and the knowledge society-Belgium, Proceedings in Manufacturing Systems – Romania, Global Journals Inc. (USA), IOSR JCE. He is author of the monograph “Decision Control, Management, and Support in Adaptive and Complex Systems: Quantitative Models. IGI Global and several chapters in “Encyclopedia of Business Analytics and Optimization”, Encyclopedia of Information Science and Technology, Fourth Edition (IGI Global) “Artificial Intelligence: Concepts, Methodologies, Tools and Applications” - IRMA USA. He has interests in the fields of decision making, utility theory, theory of measurement, stochastic approximation, machine learning, optimization and control, approaches for control, reduction and equivalent transformation of nonlinear models. He is member of International Institute of Informatics and Systemics (IIS).

Carla Pires is Professor at Universidade Lusófona's Research Center for Biosciences and Health Technologies, Portugal, and invited collaborator Faculty of Arts and Humanities of the University of

Lisbon, and Laboratory of Phonetics and Lisbon Baby Lab. Her research interests include health communication, social pharmacy, pharmacy practice, and other. <http://orcid.org/0000-0003-4526-0271>.

Julia Margarete Puaschunder studied Philosophy/Psychology (MPhil, University of Vienna, 2003), Business (MBA, Vienna University of Economics and Business, 2007), Public Administration (MPA, Maxwell School, 2008), Social and Economic Sciences (Doctor, Vienna University of Economics and Business, 2006), Natural Sciences (Doctor, University of Vienna, 2010), Law and Economics (pending). Julia M. Puaschunder has launched and administered research projects in Australia, Austria, Canada, China, Germany, Indonesia, Switzerland, and the United States. She conducted interdisciplinary science and governance projects as well as held or holds advisory, board member, evaluator, committee, contributor, observer, referee and representative privileges for the Academic Council on the United Nations System, Academy of Behavioral Finance and Economics, Alpbach Laxenburg Group, Austrian Academy of Sciences, Austrian Chamber of Commerce New York, Austrian Economic Association, Austrian Federal Ministry of Science and Research, Austrian Federal Ministry of Science, Research and Economy, Austrian General Consulate New York, Austrian Office of Science and Technology Washington D.C., Austrian Scientists in North America Association, Austrian Society for New Institutional Economics, Cambridge Scholars Publishing, Discovery Innovation Growth (DiG) Talent Development Network, EURO working group on Behavioural Operational Research, European Horizons Conference, European Union Commission, Finance, Risk and Accounting Perspectives Conference at University of Cambridge, Fritz Thyssen Foundation, Fulbright Commission, Harvard Association for Law and Mind Sciences, Harvard Club of Austria, Harvard University Center for the Environment, Horizon 2020, International Institute for Applied Systems Analysis, Janeway Center, Kollegium Kalksburg Altkalksburger Vereinigung, Netherlands Organisation for Scientific Research, Oikos International New York City Chapter, Oxford Academic Research Network, Research in Management and Learning Education Unconference, Society for International Development Vienna Chapter, Society of Authors, The Max Kade Foundation New York, The Neue Galerie New York, Tishman Environment and Design Center, the U.S. Department of Education, Vienna Foundation, Vienna International Conference on Mathematical Modelling and Viennese Opera Ball New York International Business Committee. In 2011, she served as a participant in a U.S. White House conference call on environmental justice. Before starting a Prize Fellowship in the Inter-University Consortium of New York working for the New School (Deans Office, Department of Economics, Department of Politics, Economics of Climate Change Project, Eugene Lang College, Parsons School of Design, School of Public Engagement and the Schwartz Center for Economic Policy Analysis) as well as Columbia University (Department of Economics, Graduate School of Arts and Sciences), Julia M. Puaschunder held positions at the University of Vienna and the Vienna University of Economics and Business. For several years she was an Associate of the Harvard University Faculty of Arts and Sciences and serves as Contributor to the Harvard Law School Law and Mind Sciences Initiative Situationist. At the Harvard University Center for the Environment, she conducted research on intergenerational equity in cooperation with Harvard Business School and Harvard Kennedy School. Trained as a behavioral economist with Doctorates in Social and Economic Sciences as well as Natural Sciences and Masters in Business, Public Administration and Philosophy/Psychology, she has over 15 years of experience in applied social sciences empirical research in the international arena. Julia M. Puaschunder serves as expert member of the Academic Council on the United Nations System, the European Corporate Governance Institute, and the Virtus Corporate Governance Experts Global Repository. Apart from academic appointments in Austria, Julia was a scholar at The Australian National University, Columbia University in the

About the Contributors

City of New York, Harvard University, Haskayne School of Business, Ludwig-Maximilians-University of Munich, and The Open Society Institute & Soros Foundation New York. Currently, she conducts research as a Prize Fellow in the Inter-University Consortium of New York. Throughout her academic career, Julia was invited to present her research at Harvard University, Princeton University, Columbia University, Brown University, Oxford University and Cambridge University as well as The Academic Council on the United Nations System. She published with Harvard University, Columbia University and Oxford University outlets among other distinct journals and international publishing houses (e.g., Emerald, Palgrave Macmillan, Routledge, Springer International & Nature, Vernon, Wiley). Julia organized conferences and public speakers from the Harvard Business School and Princeton University in North America and Europe. Since 2015 Julia Puaschunder supports the Economics of Climate Change Project Speaker Series hosted at The Schwartz Center for Economic Policy Analysis of The New School for Social Research in New York City. Julia helped initiate the 2017 Unconference at The New School New York in cooperation with the New School for Public Engagement and served on the Scientific Committee of the 2017 Finance, Risk and Accounting Perspectives Conference as well as the Social and Sustainable Finance and Impact Investing Conference 2017 at University of Cambridge. Julia is scheduled as scientific board member of the 2018 Vienna International Conference on Mathematical Modelling at the Technical University Vienna as well as the 2019 Annual Conference of the Academy of Behavioral Finance and Economics. Julia is included in the '2018 Marquis Who's Who in America and in the World' among the top 3% professionals around the globe. She was awarded the 2018 Albert Nelson Marquis Lifetime Achievement Award. After having captured social responsibility in corporate and financial markets in Europe and North America with attention to Financial Social Responsibility and Socially Responsible Investment; Julia Puaschunder currently pursues the idea of Eternal Equity — responding to Western world intergenerational equity constraints in the domains of environmental sustainability, overindebtedness and demographic aging with focus on law and mind sciences. Currently, Julia dedicates interest to Humanness, Automated Control and Artificial Intelligence Ethics.

Kornelije Rabuzin is a full professor of databases at the Faculty of organization and informatics, University of Zagreb, Croatia. He holds Bachelor, Master, and PhD degrees - all in Information Science. He performs research in the area of databases, data warehouses, business intelligence, and data science. He is the head of the department for theoretical and applied foundations of information science.

Monica Bixby Radu is an Assistant Professor of Sociology at Southeast Missouri State University in the Department of Criminal Justice, Social Work, and Sociology. Some of her current research interests include intimate partner violence, school safety, bullying, family and school social capital, and juvenile delinquency. Dr. Radu's work has been published in *American Behavioral Scientist*, *Child Development Perspectives*, *Sociology Compass*, and *The Journal of Public and Professional Sociology* among other scholarly journals and edited books.

Bapuji Rao is currently working as Asst. Professor of Computer Science, Engg. & Applications at Indira Gandhi Institute of Technology (IGIT), Sarang, Dhenkanal, Odisha, India. He received M.Tech (Computer Science) from Berhampur University, Berhampur, Odisha, India. He is pursuing Ph.D. (CSE) from Biju Patnaik University of Technology (BPUT), Rourkela, Odisha, India. He has published 27 papers in International Conferences which includes IEEE-6, Springer-4, Elsevier-1, and McGraw-Hill-1. He has published 8 papers in International Journals of repute. He has published four book chapters in

IGI Global, USA. His Current Research area focuses on Graph Mining, Social Network, Data Mining, Multi-Layer Graph, and attributed graph.

Jose Poças Rascão (PhD, ISCTE/ULI) is a Professor of Management Information Systems at the Polytechnic Institute of Setúbal, Portugal. It is research in the Research Unit in the development of enterprise (UNIDE) at the Lisbon University Institute (ISCTE/ULI). Since 2000 has published 16 books and chapters of books on strategy management and management of information and more than 43 publications on strategy and information management. Under his supervision, 17 Masters Theses have been successfully from 2007 to 2018, with 3 more coming up for defense in next 2 years. From 2010 to 2015 was Director of course management of distribution and logistics. He also works the private management consultant for large and medium-sized enterprises. He worked the management consult at Price Waterhouse and Coopers & Lybrand between 1989 and 1995.

Adnan Rashid received his PhD degree in Information Technology from School of Electrical Engineering and Computer Science (SEECS), National University of Science and Technology (NUST), Islamabad, Pakistan, 2019. Prior to this, he received the M.Sc. and M.Phil. degree in Electronics from the Department of Electronics, Quaid-i-Azam University (QAU), Islamabad, Pakistan, in 2008 and 2012, respectively. Currently, he is working as a Research Associate with the System Analysis and Verification (SAVE) laboratory in SEECS, NUST. He also worked as a Visiting Researcher at Hardware Verification Group (HVG), Concordia University, Canada, for 6 months in 2017. He has a strong interest in Formal Methods, with their applications in Control Systems, Analog Circuits, Biological Systems, Communication Systems and Transportation Systems. He has served as a chair of the Doctoral program at Conference on Intelligent Computer Mathematics (CICM-2017), Edinburgh, UK.

Mamata Rath, M.Tech, Ph.D. (Comp.Sc), has twelve years of experience in teaching as well as in research and her research interests include Mobile Adhoc Networks, Internet of Things, Ubiquitous Computing, VANET and Computer Security.

Maya Rathore has received her Master Degree in Computer Applications from Rajiv Gandhi Technical University, Bhopal, India and PhD in Computer Science from Devi Ahilya University Indore, India. Presently she is working as Associate Professor at Christian Eminent College, Indore (MP), India. She is having 12.4 years of teaching and 8 years of research experience. Her areas of research are Software Engineering, Service- Oriented Computing, Distributed computing and Cloud computing. She has contributed 18 research publications in various national and international conferences and journals. She has co-authored a book on OOAD and published 1 book chapters in Springer.

Sina Razvarz received the B.S. degree in Mechanical Engineering, Heat and Fluids from Islamic Azad in Bonab, Iran in 2009 and the M.S. degree in Mechanical Engineering from Islamic Azad University, Science and Research Branch, Tehran, in 2010. Now, He is studying at the Departamento de Control Automático, CINVESTAV-IPN (National Polytechnic Institute), Mexico City, Mexico, for his Ph.D. degree. His research interests include heat transfer, fluid dynamic, fuzzy equation, neural networks, and nonlinear system modeling.

Irene Rivera-Trigueros is a PhD student and research staff in training at the University of Granada.

About the Contributors

James A. Rodger is a Professor of Management Information Systems and Decision Sciences at Indiana University of Pennsylvania (IUP). He received his Doctorate in MIS from Southern Illinois University at Carbondale in 1997. Dr. Rodger has published several journal articles related to these subjects. His work has appeared in the following journals: Computers in Human Behavior, Journal of Computer Information Systems, Issues in Information Systems, IEEE Transactions on Software Engineering, International Journal of Hybrid Intelligent Systems, Information and Software Technology, Information Technology and Management, Annals of Operations Research, Communications of ACM, Computers & Operations Research, Decision Support Systems, Expert Systems with Applications, Lecture Notes in Computer Science, International Journal of Human-Computer Studies as well as several other journals.

Alexandria L. Rook is an undergraduate student at Southeast Missouri State University majoring in Criminal Justice and minoring in Spanish, with special interests in corrections and gender studies. She is interested in pursuing a career in law enforcement and has research interests in cyberbullying, racial disparities within the prison system, and policy development.

Sudhir K. Routray received his B.E. degree in electrical engineering from Utkal University, India; M.Sc. (Engineering) degree in data communications from Sheffield University, UK; and PhD in telecommunication engineering from University of Aveiro, Portugal. He has worked as a lecturer in Biju Pattnaik Technical University, Rourkela (India); Swami Vivekananda University of Technology, Bhilai (India); and Eritrea Institute of Technology, Mai Nefhi (Eritrea). He joined the Institute of Telecommunications, Aveiro in 2011 and worked there till 2015. He joined CMR Institute of Technology, Bangalore, India in Aug 2015 as a member of the faculty of Electronics and Communication Engineering. His research interests are optical networks, network science and statistical analysis of communication networks. He is a senior member of IEEE. He serves as a volunteer in IEEE Bangalore Section in IEEE Region 10. Now he works as an Associate Professor in the department of ECE in AASTU.

Khadijeh (Roya) Rouzbehani, PhD, is a Postdoctoral Fellow with teaching and research interests in policy, Collaboration, strategic communication, Public Health, Knowledge Management, and corporate social responsibility (which includes ethics and sustainability). She started teaching at the School of Management of UT in 2012, while running her own consulting center, as well. She has developed and taught courses for the MPA, and Business Administration programs. Her first book was on Social and Economical aspects of Public Health Policy and is getting the second one published which is on political factors influencing Public Health. She joined University of Victoria as a Postdoctoral fellow in 2017 to further her research and teaching in this top comprehensive university.

Nagayuki Saito is a former Policy Analyst of OECD, Directorate for Science, Technology and Industry, Special Appointment Senior Research Fellow of Ministry of Internal Affairs and Communications, Institution for Information and Communication Policy and visiting researcher of Aoyama-Gakuin University Human Innovation Research Center. He is instructor of Ochanomizu University Interdisciplinary liberal arts. He graduated from a Doctorate Program of Keio University Graduate School of Media Design and had a Master's degree of Economics at Chuo University Graduate School. He is a committee Member of the Committee for Information, Communications and Consumer Policy Division, Working Party on Information Security and Privacy in OECD. His research theme is making a safer Internet environment

for the youth. It focuses on awareness of education, making collaborative e-learning system based on theory of social constructivism; information and communication policy.

Christos Sakkas received his BSc degree in Informatics and his MSc degree in Computer Science from Department of Informatics of Athens University of Economics and Business (AUEB). Mr. Sakkas has been an active research associate of Media Net Lab at the NCSR “Demokritos” from 2013 until 2018. Since 2018 he has joined the R&D team of INFOLYSiS P.C. He has participated in many EU-funded projects, collaborating with various universities and enterprises with presentations and publications at international conferences. His current research interests include IoT, SDN, NFV, Cloud Computing, Monitoring systems and web/mobile applications and web/mobile applications including chatbots.

Wilson Sakpere received his bachelor’s degree in Electrical Engineering in 2007 from the University of Ilorin, Nigeria and master’s degree in Information Technology in 2015 from the Cape Peninsula University of Technology (CPUT), Cape Town, South Africa. He is a quality-focused researcher with a balanced background between academic and practical expertise. He is presently a doctoral researcher at the Computer Science and Engineering department, Alma Mater Studiorum, University of Bologna, Italy. His research interests include wireless networks, digital technologies, computer vision, localisation, navigation and wayfinding. The interests are directed towards applying innovations in a social context and application. As a student, engineer and lecturer, he has served in various leadership roles and engaged in community service. Hence, he has been awarded a couple of awards and commendations.

Antonio Sarasa Cabezuelo has a MS. degree on Mathematics of Computer Sciences from the Complutense University of Madrid, BS. degree on Computer Sciences from the National University of Distance Education, MS. degree on Computer Sciences from the Open University of Catalonia and CS PhD from the Complutense University of Madrid. Currently, he is an associate professor in the Computer Science School at Complutense University of Madrid, and a member of the research group ILSA (Implementation of Language-Driven Software and Applications,, <http://ilsa.fdi.ucm.es>). His research is focused on e-Learning, markup languages and Domain-specific languages. He was one of the developers of the Agrega project on digital repositories. He has published over 50 research papers in national and international conferences. Likewise, he is a member of the 36 Subcommittee of AENOR.

Theodora Saridou received her BSc in Law and her MSc in Journalism and New Media, both from Aristotle University of Thessaloniki. Her master thesis dealt with tools and applications of participatory journalism, studying, among others, the legal and ethical issues stemming from it. She is currently a PhD candidate in the School of Journalism and Mass Media Communication, researching the changing conditions in online media due to citizens’ participation in the news production process. Her research interests include participatory journalism, user-generated content, new media and online news production.

Rui Sarmento has a degree in Electrical Engineering in the Faculty of Engineering, University of Porto, and an MSc in Data Analysis and Decision Support Systems in the Faculty of Economics of the University of Porto. He has worked in several areas from an international technical support center to software development companies focusing on Communications and Intranet solutions with Linux-based Enterprise Operating Systems. He has also worked for the leading public transportation company in his hometown, Porto, as a Project Management engineer in the IT area. Rui Sarmento is also involved

About the Contributors

with the Laboratory of Artificial Intelligence and Decision Support at INESC TEC, researching Large Social Networks Analysis and Visualization for his Ph. D. thesis. He is currently also collaborating with the Statsframe team (Statistical Services and Software). Rui was previously published as a Contributing Author in the book “Integration of Data Mining in Business Intelligence Systems” (IGI Global, 2014), and he also contributed with the book “Comparative Approaches to Using R and Python for Statistical Data Analysis” (IGI Global, 2017).

Gülcan Sarp is a Geographic Information System and Remote Sensing specialist with the research interests in active tectonics and geomorphology. She obtained a B.S. in geology from Ankara University in 1998, M.S. and Ph.D. in Geodesy and Geographical Information Technologies from Middle East Technical University in 2005 and 2012 respectively. She is currently working at Süleyman Demirel University as a Associated Prof. Dr.

Richard S. Segall is Professor of Computer & Information Technology in Neil Griffin College of Business at Arkansas State University. He holds BS/MS in mathematics, MS in operations research and statistics from Rensselaer Polytechnic Institute in Troy, New York, and PhD in operations research from University of Massachusetts at Amherst. He has served on faculty of Texas Tech University, University of Louisville, University of New Hampshire, University of Massachusetts-Lowell, and West Virginia University. His research interests include data mining, Big Data, text mining, web mining, database management, and mathematical modeling. His funded research includes that by U.S. Air Force, NASA, Arkansas Biosciences Institute (ABI), and Arkansas Science & Technology Authority (ASTA), and is member of the Arkansas Center for Plant-Powered-Production (P3), Editorial Board of International Journal of Data Mining, Modelling and Management (IJDM), International Journal of Data Science (IJDS), and co-editor of Handbook of Big Data Storage and Visualization Techniques; Research and Applications in Global Supercomputing; Visual Analytics of Interactive Technologies: Applications to Data, Text & Web Mining and Open Source Software for Statistical Analysis of Big Data; all published by IGI Global.

Devjani Sen received her Doctorate, Master’s and Bachelor’s (class of Highest Honors) degrees in Psychology from Carleton University. She has nearly two decades of experience working as a social psychologist and approximately ten years of experience in human factors design and research. She has published in the areas of media, healthcare, information and communication technologies, public health crisis management, privacy, and information credibility and presented the results of her research at conferences in North America, Europe and Asia. Her work in human information technologies began in the early 2000s. Since then, she has been involved in a number of industry projects including current research trends using digital platforms. These projects comprised field research and testing of various decision support tools in the areas of healthcare, learning, human resources, and criminal analysis that best meet the needs of end-users. Numerous tools she has helped to develop have been used Canada-wide by the Department of Defence and First Responders, providing access to databases, interactive maps, checklists, incident reports, emergency response protocols. These tools have also been used by fire, emergency response, defence, and law enforcement agencies.

Mirjam Sepesy Maučec received the B.Sc. and Ph.D. degrees in computer science from the Faculty of Electrical Engineering and Computer Science, University of Maribor, in 1996 and 2001, respectively.

She was a Researcher with the Center for Interdisciplinary and Multidisciplinary Research and Studies, University of Maribor, from 1996 to 1997, and a young Researcher with the Faculty of Electrical Engineering and Computer Science, University of Maribor, under the guidance of mentor Prof. Dr. Z. Kačič, from 1997 to 2001. In 2010, she became an Associate Professor in telecommunications. She has been involved in several projects and in national research program Advanced Methods of Interaction in Telecommunication. She participated in several international and national research projects. Her research interests include machine translation, computational linguistics, and evolutionary computing.

Udai Shanker is presently Professor in the Department of Computer Sc. & Engineering of M. M. M. University of Technology, Gorakhpur-273010. For his imitation of the most modern of approaches and also for his exemplary devotion to the field of teaching, and sharing his profound knowledge with students to make better future citizen of India, he has been a role model for the new generation of academicians. Besides introduced radical and revolutionary changes that have positively impacted the database world and student community, he is a man well versed with all the intricacies of academics.

Paawan Sharma is an Asst. Professor in Dept. of ICT at PDPU. He completed Ph.D. in Engineering from Homi Bhabha National Institute, Mumbai. He is Author/co-Author of several publications in reputed International journals. He has also guided/co-guided 2 Ph.D. students in the area of Smart grid technology and Embedded Systems for Disaster management. He also has 3 Indian patents published.

Tetiana Shmelova is Doctor of Science, Professor of Department of Air Navigation Systems in National Aviation University (Ukraine). Areas of Scientific Interests: Artificial Intelligence; Mathematical Models of Decision-Making by operators in the Air Navigation System, especially in Emergency; Decision Support Systems; Research of Air Navigation system as Socio-technical system; Professional Effectiveness using Aviation Sociometry and Socionics; Management and Marketing in aviation; Information technology and Informatics of Decision-Making in the Air Navigation System; Problems of Human Factors in aviation. Author of more than 300 scientific articles, books, methodical manuals, copyright certificates, guides, monographs in fields of aviation, economics, mathematics, the theory of system. Teaching courses: Decision Making; Mathematical Programming; Effectiveness of Air Traffic Management; Effectiveness of Unmanned Systems; Artificial Intelligence.

Vaibhav Shukla has received M.Sc. in Mathematics from CSJM University Kanpur (UP), India in 2005, and the MCA degree from Kamla Nehru Institute of Technology Sultanpur (UP), India in 2009. He is currently pursuing Ph.D. in Computer Science and Engineering from Birla Institute of Technology Mesra Ranchi (Jharkhand), India. Currently, he is working as a Assistant Professor in the computer science department of Allenhouse Institute of Technology Kanpur, India. His research area includes optical packet switching design and analysis and computer networks.

Yuliya Sikirda is Associate Professor of Management, Economy, Law and Tourism Department at the Flight Academy of National Aviation University. Has graduated from the Flight Academy of National Aviation University (former State Flight Academy of Ukraine) in 2001, received a Master degree on speciality “Air Traffic Services” specialization “Air Traffic Control” (2001). Has got a diploma of PhD in Technical Sciences on speciality “Automated Control Systems and Advanced Information Technologies” (2004). PhD thesis “Modelling of Decision Support System for an Air Traffic Controller in Flight

About the Contributors

Emergency Situations”, thesis has defended in Kyiv Automation Institute. In 2006 has received an attestat of Associate Professor of Management and Economy Department. Since 2014 is the member of the specialized scientific council for the defence of dissertations for PhD in Technical Sciences on the speciality “Navigation and Traffic Control”. The author and co-author of about 180 scientific works, including three manuscripts and more than 40 articles in specialized scientific publications, three copy-right certificates on computer programs. Together with the scientific work has actively engaged in the methodological provision of the educational process, during the years of labour activity above 70 teaching and methodological works have been issued. Areas of scientific interests: increasing of the decision making efficiency by the human-operator of the Air Navigation System in flight emergencies; assessment of the influence of aviation enterprises’ internal and external management environment factors on the activity of the Socio-technical System’s operator. Teaching courses: ”Introduction to the Speciality”, “Transport and Transport Infrastructure”, “Information Systems in Management”, “Methodology of Scientific Researches”, ”Mathematical Modelling of Professional Tasks”.

Udit Singhania is right now pursuing BTech in Computer Science at VIT University, Vellore. He is involved in the research of the fields like Artificial intelligence, machine learning, and data science.

Roberta Spallone is Full Professor of Drawing at the Politecnico di Torino, Department of Architecture and Design (DAD). Graduated in Architecture at the Politecnico di Torino and obtained a Ph.D. in “Drawing and Survey of Architectural Heritage” at the Università “La Sapienza” di Roma. Currently she teaches in the “Laboratory of Drawing and Survey” and “Digital techniques of representation” in the Architecture Laurea. She also teaches a class of “Drawing and modeling aimed to analysis, interpretation and virtual reconstruction of architectural and urban heritage” in the Ph.D. program of Architectural and Landscape Heritage. Member of the Board of the Doctorate of Architectural and Landscape Heritage. Director with Marco Vitali of the book series “Drawing and Vaulted System”, Aracne Editrice. Member of the Scientific Committee of International Journal DisegnareCON and Revista EGE, and the Editorial Board of the journal Archaeology & Anthropology, Crimson Publisher and International Journal of Environmental Research and Public Health. Reviewer for many international magazines, peer-reviewed books and international congresses. Her research focuses on the fields of: history and criticism of architectural drawing, with particular attention to architectural treatises, urban survey, and digital techniques of representation aimed to graphical analyses and reconstructive modeling. Her Ph.D. thesis was awarded with the Silver Plaque, 1° Prize by Unione Italiana Disegno. Best paper FORT-MED2015_Valencia, Topic: Historical Research. Best paper UID2018_Milan, Topic: Techniques for Analysis and (Re)Building of Heritage.

G.R Sridhar MD DM FACE FRCP is the Director of Endocrine and Diabetes Centre Visakhapatnam and Adjunct Professor, Bioinformatics at the AU College of Engineering. The Editor in Chief, International Journal of Diabetes in Developing Countries, he is the Executive Editor of RSSDI Textbook of Diabetes, and is an editor of the ESI Handbook of Endocrinology. The founding editor of Indian Journal of Endocrinology and Metabolism he was the President of Research Society for the Study of Diabetes in India (2010). Dr Sridhar’s major areas of research interest are: Clinical informatics, computational biology and bioinformatics, psychosocial aspects of diabetes.

Ioannis Stergiou holds a BSc degree in Agriculture Engineering from the Aristotle University of Thessaloniki, Greece and a MSc degree in Agriculture and Environmental Sciences from the University of the Aegean, Greece. Since 2010, Ioannis has worked as agronomist and technical support IT officer at various agricultural commerce trade and IT related companies with focus on GIS and IoT smart farming through the use of IT systems for monitoring crop fields with the help of IoT sensors (light, humidity, temperature, soil moisture, etc.) and automating the irrigation systems and methodologies.

Ugrasen Suman has received PhD Degree in Computer Science from Devi Ahilya University Indore, and his Master Degree in Computer Applications from Rani Durgawati University Jabalpur India. Presently he is working as a Professor at School of Computer Science & Information. He has authored three books Software Engineering: Concepts & Practices (Cengage Learning, 2013), Software Engineering (Cengage Learning, 2018), Object Oriented Analysis & Design using UML (Cengage Learning, 2018). He has published three book chapters and 90 research papers in National & International Journals/ Conferences. He has more than 19 years of teaching and research experience.

Apostolos Syropoulos holds a B.Sc. in Physics, an M.Sc. in Computer Science, and a Ph.D. in Theoretical Computer Science. His research interests focus on computability theory, category theory, fuzzy set theory, and digital typography. He has authored or co-authored nine books and over 60 papers and articles.

Khaled Tamzini received his Ph.D. degree with honors from the Faculty of Economic Sciences and Management Sciences of Tunis in 2014. He justifies an experience of over 10 years (since 2001) as a senior trainer for the account of several national companies in the field of Human Resources Management. Dr. Tamzini is actually an Assistant professor of Strategic Human Resource Management at the IHEC of Sousse (Tunisia) where he teaches Human Resource Management and Strategic management. He is a panel member of the International Association of Strategic Management (France). He is a reviewer for several international scientific meeting as the Academy of Management Meeting, the Academy of International Business, the European Academy of Management Conference... His research interests include the Resource-Based View, Knowledge Management, Talent management, Employer branding, Human resource marketing, Human Capital, Entrepreneurship, Sustained Competitive Advantage and Strategic Human Resource Management.

George Theodoropoulos holds a BSc degree in Mathematics from the University of Athens, Greece. George has more than thirty years professional experience as computer analyst and programmer in the shipping sector participating in various research and development IT projects related to maritime software, vessel communications as well as vessel data transfer and data synchronization with offshore offices. Currently, he is a senior research and development engineer dealing with the applicability of IoT in the shipping sector.

Sonal Tiwari is a PhD candidate in the Department of Business Administration, University of Lucknow, India. She is UGC-NET/JRF (Junior Research Fellowship) qualified. Her research focuses on consumer behaviour, digital media consumption and marketing. She holds an MBA degree in Human Resources and Industrial Relations from the University of Lucknow.

About the Contributors

B. K. Tripathy is now working as a Dean of SITE Department VIT University, Vellore, India. He has received research/academic fellowships from UGC, DST, SERC and DOE of Govt. of India. Dr. Tripathy has published more than 430 technical papers in international journals, proceedings of international conferences and edited research volumes. He has produced 26 PhDs, 13 MPhils and 4 M.S (By research) under his supervision. Dr. Tripathy has published two text books on Soft Computing and Computer Graphics. Dr. Tripathy has served as the member of Advisory board or Technical Programme Committee member of several International conferences inside India and abroad. Also, he has edited two research volumes for IGI publications. He is a life/senior member of IEEE, ACM, IRSS, CSI, ACEEE, OMS and IMS. Dr. Tripathy is an editorial board member/reviewer of more than 60 journals.

George Tzanis holds a BSc, a MSc, and a PhD degree in Computer Science from the Aristotle University of Thessaloniki, Greece. He is also a family physician/general practitioner, holding a MD and a MSc in Primary Health Care from the Aristotle University of Thessaloniki.

Cyprian Ugwu is currently with the University of Nigeria, Nsukka and a Research Fellow with the University of South Africa. He has over 50 research publications in high impact international and local journals in Library and Information Science. Dr. Ugwu has made presentations at professional conferences locally and internationally. His research interests include knowledge management, ICT applications in libraries, digital communication and scholarship, research methodology and knowledge organization. He is happily married with children and his hobbies include reading, solving calculus and playing scrabble.

Immanuel Ovemeso Umukoro is a Research Fellow at the Sustainable and Inclusive Digital Financial Services initiative of the Lagos Business School, Pan-Atlantic University, Nigeria. He is also a doctoral student in information systems at the Africa Regional Centre for Information Science (ARCIS), University of Ibadan, Nigeria where he obtained a Master of Information Science degree. His Bachelor of Science degree is in Library and information science from the Delta State University, Abraka, Nigeria. He is a chartered member of the Nigerian Institute of Management and an Associate of the Centre for Global Enterprise (CGE) with a distinction in Platform Management, Strategy, and Innovation. Immanuel is a certified Digital Money Expert by the Fletcher School of Law and Diplomacy, Tufts University, USA. He also holds a certificate in interoperable and inclusive payment systems, digital financial services in emerging markets from the Digital Frontiers Institute as well as a certificate in research and grant proposal writing from the INASPIAuthorAID Foundation, USA.

Kiminori Usuki is a researcher at Center for Research on Educational Testing.

Cristóbal Vargas Jarillo received the B.S. degree from the Instituto Politécnico Nacional, Mexico, and the M.S. degree in Computer Science from University of Wisconsin, USA, and the Ph.D. degree in Mathematical Sciences from the University of Texas-Arlington. He works at Departamento de Control Automatico -CINVESTAV-IPN, México.

Rafael Vargas-Bernal received a Bachelor degree in Communications and Electronics Engineering from the University of Guanajuato in 1995, and the degrees of Master of Science and Doctorate in Science with Specialty in Electronics from the National Institute of Astrophysics, Optics and Electronics (INAOE) in 1997 and 2000, respectively. Since January 2002, he has been a professor-researcher

at the Higher Technological Institute of Irapuato (ITESI), Mexico and, particularly since 2006, he has worked in the Department of Materials Engineering where he has established himself as a researcher. He has authored 15 articles in journals, 26 chapters in books and about 100 conference articles. He is a member of the National System of Researchers (SNI-Mexico). He regularly serves as a reviewer of scientific articles in RSC Advances and Royal Society Open Science as well as Standards in Semiconductor Equipment and Materials International (SEMI). His research interests include two-dimensional materials, nanomaterials, space materials, composite materials, gas sensors and biosensors.

Andreas Veglis is Professor, head of the Media Informatics Lab at the School of Journalism & Mass Communication at the Aristotle University of Thessaloniki. He received his BSc in Physics, MSc in Electronics and Communications, and PhD in Computer Science, all from Aristotle University. His research interests include information technology in journalism, new media, course support environments, data journalism, open data and distance learning. He has published in books and international journals. He is the author or co-author of 12 books, he has published 74 papers on scientific journals and he has presented 125 papers in international and national Conferences. Professor Veglis has been involved in 30 national and international research projects.

Bruno Veloso holds a M.Sc. in Electrical and Computers Engineering, Major in Telecommunications from the Polytechnic Institute of Porto (School of Engineering) and a Ph.D. degree in Telematics from the University of Vigo, Spain. He is a researcher at the INESC TEC (Laboratory of Artificial Intelligence and Decision Support (LIAAD)). He is currently working at University of Portucalense as an Assistant Professor and he is also a collaborator at REMIT. His interests include distributed artificial intelligence, multi-agent systems, personalisation, recommendation systems and data streams.

Mário Véstias received the electrical engineering degree in 1993, and the PhD in electrical and computer engineering in 2002, both from the Technical University of Lisbon, Portugal. He is a Coordinate Professor at the Polytechnic Institute of Lisbon, School of Engineering (ISEL), Department of Electronic, Telecommunications and Computer Engineering (DEETC), where he is responsible for undergraduate and graduate courses on computer architecture and digital systems design. He is also a senior researcher at the ESDA (Electronic Systems Design and Automation) group at the research institute INESC-ID in Lisbon. His current research interests are about architectures for on-chip many-core systems for high-performance reconfigurable computing and for high-performance embedded computing and computer arithmetic.

Damjan Vljaj graduated from the Faculty of Electrical Engineering and Computer Science, University of Maribor, Slovenia, in 1998. He was awarded a Ph.D. in 2007 by the same Faculty, where he is currently employed as an Assistant Professor in the field of Telecommunications. His research interests are in the areas of speech and language technologies. He focused specifically on the research of digital signal processing in robust speech recognition in the intelligent environments and environments of fixed and mobile telephony.

Michael Gr. Voskoglou is an Emeritus Professor of Mathematical Sciences at the School of Technological Applications of the Graduate T.E.I. of Western Greece. He is the author of 17 books and of more than 500 papers published in international mathematical journals and conference proceedings.

About the Contributors

Steven Walczak, Ph.D., is an Associate Professor of Health Information Science in the School of Information and the Florida Center for Cybersecurity at the University of South Florida. His primary research interest is in applied artificial intelligence, including artificial neural networks, other machine learning methods, expert systems, heuristics, and cognitive modeling and tends to focus on healthcare related real-world problems.

Andrew Weiss is a Digital Services Librarian at California State University, Northridge.

Immo H. Wernicke served to the German Government in different positions as economic expert, political consultant, statistician and telecommunication officer. Degrees from the Faculty of Social and Economic Sciences of the University of Cologne. IT supported research and thesis on comparison of National elections in UK, France, Germany and Norway. Sales manager in a German Dax-Enterprise. Charged by the German Federal Statistical Office to implement EU- and World Bank Projects of the Acquis Communautaire on Agriculture for Turkey, Tajikistan, Zambia, South Africa, Poland and Lithuania. Charged by the German Privatization Agency (Treuhandanstalt) with missions to Poland, Albania and Moldova and with consultancies to international delegations and SMEs on the transformation to market economies. Economist and statistician at a Governmental Research Institute with focus on GDR-economy and COMECON countries. Member of International Statistical Institute (ISI), German Statistical Association, German Council of Foreign Relations, German NATO Association. Former deputy member of German Statistical Advisory Committee to the Government. Publications: Financial Crisis and Official Statistics, publ. IGI. Quality of Statistics, publ. GSMI. Economic Growth, publ. GSMI. Transformation of GDR's Economy. Contribution to the Manual of Privatization and Transformation funded by the German Ministry of Finance.

Idongesit Williams is a Post-Doctoral researcher at Center for Communication, Media and Information Technologies (CMI) located at Aalborg University Copenhagen. He holds a Bachelor in Physics, a Master degree in Information and Communications Technologies and a Ph.D. He has since 2010 researched into Knowledge Management, Organizational Learning, socioeconomic, socio-technical related to Information and Communications Technologies. He has authored and co-authored more than 30 research publications, including journal papers, books, book chapters, conference papers and magazine articles. He is the co-editor of the Books, The African Mobile Story, and the Handbook on ICT for developing countries:5G perspectives. He has organized conferences like the CMI annual conference and the CMI/GTUC conferences.

Yair Wiseman received the M.Sc. (summa cum laude) and Ph.D. degrees from Bar-Ilan University. He carried out his first Post-Doc research at the Hebrew University of Jerusalem, and the second Post-Doc research at Georgia Institute of Technology. His research interests include autonomous vehicles, intelligent transportation systems, embedded systems, real-time systems, computational transportation science, operating systems, and process scheduling. Dr. Wiseman has authored two books. He is on the editorial board of several journals, a member of dozens of conference committees and a reviewer of many scholarly journals. Dr. Wiseman has been teaching in many institutes including Bar-Ilan University, The Hebrew University of Jerusalem and Israel Aircraft Industry and has been supervising many graduate students. An interesting point is that Albert Einstein is Dr. Wiseman's academic great-great-grandfather (i.e. the advisor of the advisor of the advisor of Dr. Wiseman's advisor). Dr. Wiseman has

collaborated with other partners and received research grants to run an active laboratory from inter alia Sun Microsystems, Intel, and Polak Foundation. Dr. Wiseman is an international expert who has reviewed and evaluated several large projects of the European Union, Israel Science Foundation, Marie Skłodowska-Curie actions in Ireland and Ministry of Education and Science of Kazakhstan. His papers have been published in many venues around the world.

Sam Wong is an International Development Scholar. He obtained his PhD in Development Studies at Bradford University, UK. Before he teaches at University College Roosevelt, the Netherlands, he spent 15 years at Liverpool, Lees and Bradford Universities, UK. His research interests include development politics, power, gender and technologies. His research areas include SSA (Ghana, Nigeria, Uganda) and South Asia (Bangladesh and India).

Michelle F. Wright, Ph.D., is a Research Associate at The Pennsylvania State University and a research fellow at Masaryk University in Brno, the Czech Republic. Her research focus is on the contextual factors which influence children's, adolescents', and young adults' involvement in aggressive behaviors, with a special interest in social goals, peer status, and cultural values. She has published on these topics, with her most recent work focused on culture and anonymity, and their role in cyberbullying among adolescents.

Gen'ichi Yasuda joined Information Science and Control Engineering Course in Department of Mechanical Engineering, Faculty of Engineering, at Nagasaki Institute of Applied Science, Japan as a Research Assistant, in 1983. He was a Professor in Department of Mechanical Engineering during 1996-2005, a Professor in Department of Human and Computer Intelligence, Faculty of Informatics during 2005-2010, and also a Professor in Division of Instrument and Control, Department of Electronics and Information Technology, Graduate School of Engineering during 1996-2010. He is now a Guest Professor at Nagasaki Institute of Applied Science. He is a recipient of CACS International Automatic Control Conference Best Paper Award in 2009. He also served as session chairman in many international conferences. He originated the frontier researches on non-centralized systems and grouping robots as a doctoral dissertation at Tokyo Institute of Technology since 1971. His current research projects include a multi-microcomputer based development of automated noodle making machines.

Szde Yu is an associate professor of criminal justice at Wichita State University. He leads a Cyber Lab in conducting research on digital forensics and cyber profiling. He holds a Ph.D. in Criminology and several computer forensics certificates from the US Department of Defense as well as private sectors.

Andrej Zgank received his Ph.D. from the University of Maribor, Slovenia, in 2003 and is now an Associate Professor in the field of Telecommunications. His research interests are in the areas of advanced telecommunication services and applications design, speech and language technologies and digital signal processing. He is a member of IEEE, ISCA, and SDJT.

Tawanda Zinyama is the current Chairman and Senior Lecturer of Public Administration in the Department of Political and Administrative Studies at the University of Zimbabwe. He received a PhD degree from the University of Zimbabwe in Zimbabwe. His research interests include public administration and institutional governance, public procurement, corruption, public policy, local government

About the Contributors

management, public sector management reforms, democratic governance and public finance management. He has supervised several MPA and three PhD students in the discipline of public administration and public policy.
